**Abstract:** Experiments on the preparation of the new mixed cations  $\text{XeF}_5\text{M}(\text{AF}_6)_3$  (M = Cu, Ni; A = Cr, Nb, Ta, Ru, Rh, Re, Os, Ir, Pt, Au, As),  $\text{XeF}_5\text{M}(\text{SbF}_6)_3$  (M = Sn, Pb), and  $\text{XeF}_5\text{M}(\text{BF}_4)_x(\text{SbF}_6)_{3-x}$  (x = 1, 2, 3; M = Co, Mn, Ni, Zn) salts were successful only in the preparation of  $\text{XeF}_5\text{Ni}(\text{AsF}_6)_3$ . In other cases, mixtures of different products, mostly  $\text{XeF}_5\text{AF}_6$  and  $\text{XeF}_5\text{A}_2\text{F}_{11}$  salts, were obtained. The crystal structures of  $\text{XeF}_5\text{Ni}(\text{AsF}_6)_3$ ,  $\text{XeF}_5\text{TaF}_6$ ,  $\text{XeF}_5\text{RhF}_6$ ,  $\text{XeF}_5\text{IrF}_6$ ,  $\text{XeF}_5\text{Nb}_2\text{F}_{11}$ ,  $\text{XeF}_5\text{Ta}_2\text{F}_{11}$ , and  $[\text{Ni}(\text{XeF}_2)_2](\text{IrF}_6)_2$  were determined for the first time on single crystals at 150 K by X-ray diffraction. The crystal structures of  $\text{XeF}_5\text{NbF}_6$ ,  $\text{XeF}_5\text{PtF}_6$ ,  $\text{XeF}_5\text{RuF}_6$ ,  $\text{XeF}_5\text{AuF}_6$ , and  $(\text{Xe}_2\text{F}_{11})_2(\text{NiF}_6)$  were redetermined by the same method at 150 K. The crystal structure of  $\text{XeF}_5\text{RhF}_6$  represents a new structural type in the family of  $\text{XeF}_5\text{AF}_6$  salts, which crystallize in four different structural types. The  $\text{XeF}_5\text{A}_2\text{F}_{11}$  salts (M = Nb, Ta) are not isotypic and both represent a new structure type. They consist of  $[\text{XeF}_5]^+$  cations and dimeric  $[\text{A}_2\text{F}_{11}]^-$  anions. The crystal structure of  $[\text{Ni}(\text{XeF}_2)_2](\text{IrF}_6)_2$  is a first example of a coordination compound in which  $\text{XeF}_2$  is coordinated to the  $\text{Ni}^{2+}$  cation.

## 1. Introduction

The synthesis of  $\text{XeF}_6$  was first described in 1962 [1]. It was prepared by the reaction between xenon and fluorine (molar ratio 1:20) at 700 °C and a pressure of ~200 bar  $\text{F}_2$ . Later systematic studies showed that  $\text{XeF}_6$  can be prepared under milder conditions (molar ratio 1:10; 200 °C; and a total pressure of 33 bar) [2]. In general,  $\text{XeF}_6$  is prepared by heating a mixture of Xe and  $\text{F}_2$  (molar ratio 1:20) at 300 °C and a total pressure of ~50 bar [3]. In the presence of a  $\text{NiF}_2$  catalyst,  $\text{XeF}_6$  forms explosively from the gaseous mixture of xenon and fluorine in a molar ratio of 1:5 already at 120 °C [4]. An alternative method with high yield for the preparation of high-purity  $\text{XeF}_6$  is the reaction between Xe and  $\text{F}_2$  at low pressure and high filament temperature in a “hot wire” reactor [5]. At room temperature,  $\text{XeF}_6$  is solid ( $T_{\text{m.p.}} = 49.48$  °C,  $T_{\text{b.p.}} = 75.57$  °C) with a vapor pressure of about 0.03 bar at 23 °C [6]. The color of solid  $\text{XeF}_6$  has been reported to range from colorless to intense yellow. An explanation for these color variations of solid  $\text{XeF}_6$  is not apparent to date [7]. Liquid  $\text{XeF}_6$  and its vapors are yellow-green [6]. There are six, possibly seven, different modifications of solid  $\text{XeF}_6$  [7]. In  $\text{CF}_2\text{Cl}_2/\text{SO}_2\text{ClF}$  solution,  $\text{XeF}_6$  exists as a tetramer  $(\text{XeF}_6)_4$  [8], while in the gas phase  $\text{XeF}_6$  exists as a monomer [9–11]. The presence of a sterically active free valence electron pair on Xe leads to the  $\text{XeF}_6$  molecule being fluxional [12]. Consequently, the structure of monomeric  $\text{XeF}_6$  has been a major challenge for theoretical computational chemistry [12–17]. Experiments have clearly shown that  $\text{XeF}_6$  is not octahedral ( $O_h$ ) but most likely has the shape of a slightly distorted octahedron ( $C_{3v}$ ), naturally in a dynamical form [18]. Both conformers are energetically very close to each other [15]. Because of the low barrier of interconversion,  $\text{XeF}_6$  is a highly fluxional molecule that rapidly converts between the 8-fold degenerate  $C_{3v}$  structures via the octahedral minimum even at low temperatures [15]. In further studies,  $\text{XeF}_6$  was theoretically shown to exhibit a genuine quantum mechanical fluorine tunneling rearrangement, where it “jumps”

rapidly between isomers even near 0 K [16]. In solid argon and neon matrices, there are significant interactions between isolated XeF<sub>6</sub> monomers and the noble gas host [15]. The results of infrared spectroscopy of XeF<sub>6</sub> in Ne matrix, supported by theoretical calculations, agreed with the C<sub>3v</sub> conformer [15].

Shortly after the first report on the synthesis of XeF<sub>6</sub>, it was found that XeF<sub>6</sub> is a good fluoride ion donor that reacts with Lewis acids AF<sub>5</sub> (A = As, Sb, Pt, V, P) to form *n*XeF<sub>6</sub>·AF<sub>5</sub> adducts [19–23]. Crystal structure determination of XeF<sub>6</sub>·PtF<sub>5</sub> revealed a molecular geometry consistent with the ionic formula [XeF<sub>5</sub>]<sup>+</sup>[PtF<sub>6</sub>]<sup>−</sup> [24]. The compounds XeF<sub>6</sub>·2AF<sub>5</sub> are also [XeF<sub>5</sub>]<sup>+</sup> salts [25], while the compounds 2XeF<sub>6</sub>·AF<sub>5</sub> are [Xe<sub>2</sub>F<sub>11</sub>]<sup>+</sup> salts [26–28]. The next step was the discovery that XeF<sub>5</sub>AF<sub>6</sub> salts can bind neutral molecules as XeF<sub>2</sub> [29–31]. Later, this was extended to HF [32], XeOF<sub>4</sub> [33], and even KrF<sub>2</sub> [32]. Recently, the XeF<sub>5</sub>SbF<sub>6</sub> salt was also found to react with other MSbF<sub>6</sub> and M(SbF<sub>6</sub>)<sub>2</sub> salts to give XeF<sub>5</sub>M(SbF<sub>6</sub>)<sub>2</sub> (M = NO<sub>2</sub><sup>+</sup>, Rb<sup>+</sup>, Cs<sup>+</sup>) [28,34], XeF<sub>5</sub>M(SbF<sub>6</sub>)<sub>3</sub> (M<sup>2+</sup> = Mg, Mn, Co, Ni, Cu, Zn, Pd), and (XeF<sub>5</sub>)<sub>3</sub>[M(HF)<sub>2</sub>](SbF<sub>6</sub>)<sub>7</sub> (M = Hg) [34,35] or even more complex salts (H<sub>3</sub>O)(XeF<sub>5</sub>)<sub>2</sub>M<sub>2</sub>(SbF<sub>6</sub>)<sub>7</sub>·*n*HF (M = Ca, Cd) [36] and (O<sub>2</sub>)(XeF<sub>5</sub>)<sub>2</sub>Sr<sub>4</sub>(SbF<sub>6</sub>)<sub>11</sub>·8HF [36] with three different cations. In addition, mixed anion salts Cs[XeF<sub>5</sub>][Bi<sub>*x*</sub>Sb<sub>1−*x*</sub>F<sub>6</sub>] [28] and [XeF<sub>5</sub>][As<sub>1−*x*</sub>Sb<sub>*x*</sub>F<sub>6</sub>] (*x* ~ 0.5 and 0.7) [37] have also been reported.

XeF<sub>6</sub> is a stronger oxidizing and fluorinating agent than XeF<sub>2</sub> and XeF<sub>4</sub>. Theoretically, XeF<sub>6</sub> could be used as a fluorinating agent. Unfortunately, XeF<sub>6</sub> and its XeF<sub>5</sub><sup>+</sup> salts are very sensitive to moisture. When they are exposed to water, they hydrolyze and eventually form XeO<sub>3</sub>. The latter is an unstable compound that is extremely sensitive to impact and poses a dangerous explosion hazard when in contact with organic materials. For this reason, XeF<sub>6</sub> and its XeF<sub>5</sub><sup>+</sup> salts currently have no practical significance.

This contribution reports the results of experiments on the preparation of XeF<sub>5</sub>M(SbF<sub>6</sub>)<sub>3</sub> (M = Sn, Pb), XeF<sub>5</sub>M(BF<sub>4</sub>)<sub>*x*</sub>(SbF<sub>6</sub>)<sub>3−*x*</sub> (*x* = 1, 2, 3; M = Co, Mn, Ni, Zn), and XeF<sub>5</sub>M(AF<sub>6</sub>)<sub>3</sub> salts (M = Cu, Ni; A = Cr, Nb, Ta, Ru, Rh, Re, Os, Ir, Pt, Au, As). The experiments were successful only in the preparation of XeF<sub>5</sub>Ni(AsF<sub>6</sub>)<sub>3</sub>, and many other phases were obtained in other experiments. The crystal structures of XeF<sub>5</sub>Nb<sub>2</sub>F<sub>11</sub>, XeF<sub>5</sub>TaF<sub>6</sub>, XeF<sub>5</sub>Ta<sub>2</sub>F<sub>11</sub>, XeF<sub>5</sub>RhF<sub>6</sub>, XeF<sub>5</sub>IrF<sub>6</sub>, and Ni(XeF<sub>2</sub>)<sub>2</sub>(IrF<sub>6</sub>)<sub>2</sub> were determined for the first time. The crystal structures of XeF<sub>5</sub>NbF<sub>6</sub> [30], XeF<sub>5</sub>PtF<sub>6</sub> [24], XeF<sub>5</sub>RuF<sub>6</sub> [38], XeF<sub>5</sub>AuF<sub>6</sub> [39], and (Xe<sub>2</sub>F<sub>11</sub>)<sub>2</sub>(NiF<sub>6</sub>) [40] were redetermined with higher accuracy than previously reported.

## 2. Results

### 2.1. Attempted Preparation of the Salts XeF<sub>5</sub>M(AF<sub>6</sub>)<sub>3</sub> (M = Cu, Ni; A = Cr, Nb, Ta, Ru, Rh, Re, Os, Ir, Pt, Au, As), XeF<sub>5</sub>M(SbF<sub>6</sub>)<sub>3</sub> (M = Sn, Pb), and XeF<sub>5</sub>M(BF<sub>4</sub>)<sub>*x*</sub>(SbF<sub>6</sub>)<sub>3−*x*</sub> (*x* = 1, 2, 3; M = Co, Mn, Ni, Zn)

The proposed synthetic methods lead to a mixture of substances. The work carried out is an X-ray diffraction study of some crystal phases of these mixtures. In addition, some of the products were also confirmed by Raman spectroscopy (Supplementary Materials).

Reactions between XeF<sub>2</sub>, MF<sub>2</sub> (M = Cu, Ni), AsF<sub>5</sub>, and UV-irradiated F<sub>2</sub> in anhydrous hydrogen fluoride (aHF) resulted in clear colorless (Cu) and yellow (Ni) solutions (Table S1). In the case of nickel, single crystals of XeF<sub>5</sub>Ni(AsF<sub>6</sub>)<sub>3</sub> were obtained upon crystallization (Table 1), while in the case of copper a mixture of single crystals of XeF<sub>5</sub>AsF<sub>6</sub> [41] and CuFAsF<sub>6</sub> [42] was observed in the crystallization product. In all other experiments where mixtures of XeF<sub>2</sub>/MF<sub>2</sub> (M = Ni, Cu) with addition of AF<sub>3</sub> (A = Cr, Au), AF<sub>5</sub> (A = Nb, Ta), or metal powder A (A = Re, Ru, Rh, Os, Ir, Pt) were treated with UV-irradiated F<sub>2</sub> (Table S1), the insoluble material did not disappear even after several days. For crystallization, the clear supernatant, which contained no visible sediments, was decanted into the side arm of the double-arm crystallization vessel. Only single crystals of XeF<sub>5</sub>AF<sub>6</sub> (A = Nb, Ta, Ru, Rh, Ir, Pt, Au) and XeF<sub>5</sub>A<sub>2</sub>F<sub>11</sub> salts (A = Nb, Ta) were grown from the corresponding solutions (Table S1). In the case of Ru and Pt, traces of O<sub>2</sub>AF<sub>6</sub> salts (A = Ru, Pt) [43,44] were also present. Although the remaining insoluble solids were not characterized, it can be assumed that they probably consisted of M(AF<sub>6</sub>)<sub>2</sub> salts (M = Ni, Cu; A = Nb, Ta, Ru, Rh, Ir, Pt, Au). Of these, only Cu(AuF<sub>6</sub>)<sub>2</sub> and Ni(AuF<sub>6</sub>)<sub>2</sub> [45] are known, while the others have not yet been synthesized. Similar to the M[AuF<sub>6</sub>]<sub>2</sub> salts, unlike the M(AF<sub>6</sub>)<sub>2</sub> salts (A = As, Sb) [46],

they are probably not well soluble or they are insoluble in anhydrous HF. For the  $M(\text{AF}_6)_2$  salts ( $M = \text{Ni, Cu; A} = \text{Nb, Ta, Ru, Rh, Os, Ir, Pt}$ ), their lattice energy appears to overcome the solvation energy. This would explain their insolubility in aHF and the preferential formation of mixtures of  $M(\text{AF}_6)_2$  (insoluble in aHF) and  $\text{XeF}_5\text{AF}_6$  (soluble in aHF) instead of  $\text{XeF}_5M(\text{AF}_6)_3$  salts ( $M = \text{Cu, Ni; A} = \text{Nb, Ta, Ru, Rh, Ir, Pt, Au}$ ).

**Table 1.** Summary of crystal data and refinement results for  $\text{XeF}_5\text{AF}_6$  ( $A = \text{Nb, Ta, Ru, Rh, Ir, Pt, Au}$ ).

<sup>a</sup> GOF =  $[\sum w(F_o^2 - F_c^2)^2 / (N_o - N_p)]^{1/2}$ , where  $N_o$  = no. of reflns and  $N_p$  = no. of refined parameters.

<sup>b</sup>  $R_1 = \sum ||F_o| - |F_c|| / \sum |F_o|$ . <sup>c</sup>  $wR_2 = [\sum w(F_o^2 - F_c^2)^2 / \sum (w(F_o^2)^2)]^{1/2}$ .

In the  $\text{XeF}_2/\text{NiF}_2/\text{Ir}/\text{UV}$ -irradiated  $\text{F}_2/\text{aHF}$  system single crystals of  $\text{XeF}_5\text{IrF}_6$  and  $\text{Ni}(\text{XeF}_2)_2(\text{IrF}_6)_2$  were found in the same batch after crystallization (Table S1). This means that either the  $\text{F}_2$  concentration was too low to oxidize all of the  $\text{Xe}(\text{II})$  to  $\text{Xe}(\text{VI})$ , or that partial reduction of  $\text{Xe}(\text{VI})$  occurred during crystallization.

In the  $\text{XeF}_2/\text{NiF}_2/\text{Re}/\text{UV}$ -irradiated  $\text{F}_2$  system, few single crystals of  $(\text{Xe}_2\text{F}_{11})_2(\text{NiF}_6)$  were detected as crystallization product (Table S1). When pure Re powder is treated with UV-irradiated  $\text{F}_2$  in aHF, it oxidizes to volatile  $\text{ReF}_6$  [47]. The latter does not react in aHF even with a very good fluorine ion donor such as CsF [47]. In the  $\text{XeF}_2/\text{NiF}_2/\text{Re}/\text{UV}$ -irradiated  $\text{F}_2/\text{aHF}$  system, all the Re is oxidized to inert gaseous  $\text{ReF}_6$ . When the  $\text{NiF}_2/\text{F}_2$  reaction mixture in aHF is irradiated with UV light, the particles of pale yellow-green  $\text{NiF}_2$ , which is insoluble in aHF, turn black. This indicates that  $\text{NiF}_2$  is first fluorinated to  $\text{NiF}_{2+x}$  ( $x \leq 1$ ) [47]. When only  $\text{XeF}_2$  ( $\text{Xe}^{\text{II}}$ ) is present without other compounds,  $\text{XeF}_2$  is oxidized to  $\text{Xe}^{\text{IV}}$  ( $\text{XeF}_4$ ) by elemental fluorine under UV light in aHF [47]. Our experiment has shown

that in the presence of Ni(II) and Xe(II) as reagents, oxidation to Ni(IV) and Xe(VI) occurs, giving  $(Xe_2F_{11})_2(NiF_6)$  [40]. The  $A'_2NiF_6$  salts ( $A' = Li, Na, K, Cs$ ) can also be prepared by oxidation of  $NiF_2$  at about 20 °C by sunlight or UV-irradiated  $F_2$  in liquid aHF containing dissolved alkali metal fluorides (LiF, NaF, KF, CsF) [48].

In the  $XeF_2/CuF_2/Os/UV$ -irradiated  $F_2/HF$  system, a colorless solution was observed over white insoluble material. Upon cooling the reaction vessel to 77 K, a strong yellow coloration of the solid aHF was observed, indicating the presence of yellow  $OsF_6$  [49]. When crystallized from the decanted clear solution, only two small colorless crystals were formed. One of them was detected as  $XeF_4$  by Raman spectroscopy, while the other exploded on the diffractometer goniometer.

An attempt to prepare  $XeF_5Cu(CrF_6)_3$  or to detect the formation of  $XeF_5CrF_6$  salt was unsuccessful. Crystallization yielded only single crystals of  $(XeF_5CrF_5)_4 \cdot XeF_4$  [50]. Although  $A'CrF_6$  salts ( $A' = Na, K, Rb, Cs$ ) are known [51], the salt  $XeF_5^+CrF_6^-$  is not. The reaction between  $CrF_5$  and  $XeF_6$  proceeds at room temperature in aHF with release of fluorine and formation of  $XeF_5CrF_5$  [52]. In the presence of  $XeF_4$ , the very stable  $(XeF_5CrF_5)_4 \cdot XeF_4$  is formed [50].

Attempts to prepare  $XeF_5M(SbF_6)_3$  salts ( $M = Sn, Pb$ ) failed (Table S1). The crystals grown from clear decanted solutions corresponded mainly to  $XeF_5Sb_2F_{11}$  [25] and  $XeF_5SbF_6$  [25]. Various approaches to prepare  $XeF_5M(BF_4)_x(SbF_6)_{3-x}$  salts ( $x = 1, 2, 3$ ;  $M = Co, Mn, Ni, Zn$ ) also failed. In the case of Co and Mn, oxidation of M(II) to M(III) occurred, while only crystals of  $XeF_5SbF_6$  and  $XeF_5Sb_2F_{11}$  were found between powdered material. In an attempt to prepare  $(XeF_5)Ni(BF_4)_3$ , only single crystals of  $XeF_5BF_4$  [28] were found (Table S1).

## 2.2. Crystal Structures of the Salts $XeF_5AF_6$ ( $A = Nb, Ta, Ru, Rh, Ir, Pt, Au$ ), $XeF_5A_2F_{11}$ ( $A = Nb, Ta$ ), $(Xe_2F_{11})_2(NiF_6)_2$ , and $Ni(XeF_2)_2(IrF_6)_2$

Crystal structures were determined on single crystals by X-ray diffraction. Details of the data acquisition parameters and other crystallographic information for the salts  $XeF_5AF_6$  ( $A = Nb, Ta, Ru, Rh, Ir, Pt, Au$ ),  $XeF_5A_2F_{11}$  ( $A = Nb, Ta$ ), and  $(Xe_2F_{11})_2(NiF_6)_2$  and  $Ni(XeF_2)_2(IrF_6)_2$  are given in Tables 1 and 2. The crystal structures of  $XeF_5NbF_6$  [30],  $XeF_5PtF_6$  [24],  $XeF_5RuF_6$  [38],  $XeF_5AuF_6$  [39], and  $(Xe_2F_{11})_2(NiF_6)$  [40] were redetermined at low temperature with higher accuracy than previously reported.

**Table 2.** Summary of crystal data and refinement results for  $XeF_5A_2F_{11}$  ( $A = Nb, Ta$ ),  $XeF_5Ni(AsF_6)_3$ ,  $(Xe_2F_{11})_2(NiF_6)_2$ , and  $Ni(XeF_2)_2(IrF_6)_2$ .

### 3. Discussion

#### 3.1. Crystal Structures of XeF<sub>5</sub>AF<sub>6</sub> (A = Nb, Ta, Ru, Rh, Os, Ir, Pt, Au, As, Sb)

Prior to this study, the crystal structures of XeF<sub>5</sub>NbF<sub>5</sub> (293 K) [30], XeF<sub>5</sub>RuF<sub>5</sub> (RT; room temperature) [38], XeF<sub>5</sub>PtF<sub>5</sub> (RT) [24], XeF<sub>5</sub>AuF<sub>5</sub> (RT) [39], XeF<sub>5</sub>AsF<sub>6</sub> (80 K, 100 K, 150 K, 298 K) [37,41,53], XeF<sub>5</sub>SbF<sub>6</sub> (150 K, 296 K) [25,37], and mixed anion [XeF<sub>5</sub>][As<sub>0.3</sub>Sb<sub>0.7</sub>F<sub>6</sub>] (200 K, 295 K) and [XeF<sub>5</sub>][As<sub>0.5</sub>Sb<sub>0.5</sub>F<sub>6</sub>] (150 K, 295 K) salts [37] were known. X-ray powder diffraction (XPD) images showed that XeF<sub>5</sub>AF<sub>6</sub> (A = Os, Ir, Pt, and Ru) are isotypic [39].

The crystal structures of XeF<sub>5</sub>AF<sub>5</sub> (A = Nb, Ru, Pt, Au) determined at 150 K are the same as at room temperature. The crystal structure of XeF<sub>5</sub>IrF<sub>5</sub> agrees with the XPD data [39], while the crystal structures of XeF<sub>5</sub>TaF<sub>6</sub> and XeF<sub>5</sub>RhF<sub>6</sub> have been determined for

the first time. Based on the results of this study and the data known from the literature, the crystal structures of the  $\text{XeF}_5\text{AF}_6$  salts ( $A = \text{Nb, Ta, Ru, Rh, Os, Ir, Pt, Au, As, Sb}$ ) can be classified into four types of structures (type I, II, III, and IV).

### 3.1.1. Type I; $\text{XeF}_5\text{AF}_6$ ( $A = \text{Nb, Ta, Ru, Os, Ir, Pt, Sb}$ ) Salts

The crystal structure of  $\text{XeF}_5\text{PtF}_6$  was described as the first example of type I [24]. The crystal structures of the salt  $\text{XeF}_5\text{AF}_6$  ( $A = \text{Nb, Ta, Ru, Os, Ir, Sb}$ ) are isotypic to this type (Tables 1 and 3). The members of type I crystallize in the orthorhombic  $Pnma$  space group, in which the asymmetric structural unit consists of a crystallographically unique  $[\text{XeF}_5]^+$  cation and  $[\text{AF}_6]^-$  anion (Figure 1).

**Figure 1.** Two different views of the packing of  $[\text{XeF}_5]^+$  cations and  $[\text{IrF}_6]^-$  anions in the crystal structure of  $[\text{XeF}_5][\text{IrF}_6]$  (type I).

Each  $[\text{XeF}_5]^+$  cation exhibits the typical geometry, i.e., a pseudo-octahedral  $\text{AX}_5\text{E}$  VSEPR arrangement of the bond pairs (X) and the lone pair (E). The  $\text{Xe}-\text{F}_{\text{ax}}$  bonds are shorter than the other four  $\text{Xe}-\text{F}_{\text{eq}}$  distances (Table 4, Figure 2). Each  $\text{XeF}_5$  unit forms four secondary contacts with the fluorine atoms of four  $\text{AF}_6$  groups (Figure 2). Each  $[\text{AF}_6]^-$  anion participates in four secondary contacts with four different  $\text{XeF}_5$  groups (Figure 2).

**Figure 2.** Secondary contacts between the  $[\text{XeF}_5]^+$  cations and  $[\text{IrF}_6]^-$  anions in the crystal structure of  $[\text{XeF}_5][\text{IrF}_6]$  (type I).

### 3.1.2. Type II; $\text{XeF}_5\text{AF}_5$ (A = As, Au) Salts

The crystal structures of  $\text{XeF}_5\text{AuF}_6$  and the monoclinic form of  $\text{XeF}_5\text{AsF}_6$  are examples of type II (Tables 1 and 4). They crystallize in the monoclinic space group  $P2_1/c$ . The asymmetric structural unit of type II consists of a crystallographically equivalent  $[\text{XeF}_5]^+$  cation and an  $[\text{AF}_6]^-$  anion (Figure 3).

**Figure 3.** Two different views of the packing of  $[\text{XeF}_5]^+$  cations and  $[\text{AuF}_6]^-$  anions in the crystal structure of  $[\text{XeF}_5][\text{AuF}_6]$  (type II).

The geometry of the  $[\text{XeF}_5]^+$  in the salts of type II is the same as in type I [ $d(\text{Xe}-\text{F}_{\text{ax}}) < d(\text{Xe}-\text{F}_{\text{eq}})$ ; Table 4, Figure 4), while the number of secondary contacts between  $[\text{XeF}_5]^+$  cations and  $[\text{AF}_6]^-$  anions is different. In type II, each  $[\text{XeF}_5]^+$  cation forms three secondary contacts with the fluorine atoms of two  $\text{AF}_6$  groups and each  $[\text{AF}_6]^-$  anion participates in three secondary contacts with two different  $\text{XeF}_5$  groups (Figure 4).

**Figure 4.** Secondary contacts between the  $[\text{XeF}_5]^+$  cations and  $[\text{AuF}_6]^-$  anions in the crystal structure of  $[\text{XeF}_5][\text{AuF}_6]$  (type II).

### 3.1.3. Type III; $\text{XeF}_5\text{AF}_5$ (A = Rh) Salts

The crystal structure of  $\text{XeF}_5\text{RhF}_6$  is the only representative of type III (Tables 1 and 4). It crystallizes in the orthorhombic space group  $Pbca$ . The asymmetric structural unit of type III consists of a crystallographically equivalent  $[\text{XeF}_5]^+$  cation and an  $[\text{AF}_6]^-$  anion (Figure 5).

**Figure 5.** Two different views of the packing of  $[\text{XeF}_5]^+$  cations and  $[\text{RhF}_6]^-$  anions in the crystal structure of  $[\text{XeF}_5][\text{RhF}_6]$  (type III).

The geometry of the  $[\text{XeF}_5]^+$  in the type III salts is similar to that in the type I and II compounds ( $d(\text{Xe}-\text{F}_{\text{ax}}) < d(\text{Xe}-\text{F}_{\text{eq}})$ ; Table 4, Figure 6), while the nature of the secondary interaction contacts between the  $[\text{XeF}_5]^+$  cations and the  $[\text{AF}_6]^-$  anions is different. In type III, each  $[\text{XeF}_5]^+$  cation forms four secondary contacts with the fluorine atoms of three  $\text{AF}_6$  groups, while each  $[\text{AF}_6]^-$  anion participates in four secondary contacts with three different  $\text{XeF}_5$  groups (Figure 6).

**Figure 6.** Secondary contacts between the  $[\text{XeF}_5]^+$  cations and  $[\text{RhF}_6]^-$  anions in the crystal structure of  $[\text{XeF}_5][\text{RhF}_6]$  (type III).

### 3.1.4. Type IV; Orthorhombic $\text{XeF}_5\text{AsF}_6$ and Mixed Anionic $[\text{XeF}_5][\text{As}_{0.3}\text{Sb}_{0.7}\text{F}_6]$ and $[\text{XeF}_5][\text{As}_{0.5}\text{Sb}_{0.5}\text{F}_6]$ Salts

The crystal structure of  $\text{XeF}_5\text{AsF}_6$  was first determined at room temperature [41] and later redetermined at 150 K [37]. When the crystal first measured at 150 K was cooled to 80 K and data were collected, no phase transition was observed [37]. In both cases, only a monoclinic phase was obtained (150 K;  $P2_1/c$ ,  $Z = 4$ ,  $a = 5.8222(6) \text{ \AA}$ ,  $b = 16.3566(15) \text{ \AA}$ ,  $c = 7.9247(8) \text{ \AA}$ ,  $\beta = 90.729(9)^\circ$ ). However, single crystals of orthorhombic  $\text{XeF}_5\text{AsF}_6$  (Table 8) crystallized from aHF solution between 22 and  $-30^\circ\text{C}$  [53]. The corresponding aHF solution was prepared by redox decomposition of  $[\text{FKrFXeF}][\text{AsF}_6] \cdot 0.5\text{KrF}_2 \cdot 2\text{HF}$  heated stepwise and four different times, from  $-65^\circ\text{C}$  to  $22^\circ\text{C}$ . The asymmetric structural unit consists of two crystallographically nonequivalent  $[\text{XeF}_5]^+$  cations and two  $[\text{AsF}_6]^-$  anions [53].

**Table 8.** Summary of crystal data for the orthorhombic  $\text{XeF}_5\text{AsF}_6$  and mixed anion  $[\text{XeF}_5][\text{As}_{0.3}\text{Sb}_{0.7}\text{F}_6]$  and  $[\text{XeF}_5][\text{As}_{0.5}\text{Sb}_{0.5}\text{F}_6]$  salts.

<sup>a</sup> Ref. [53]. <sup>b</sup> Ref. [37].

Similar unit cell parameters (Table 8) were determined for orthorhombic  $[\text{XeF}_5][\text{As}_{0.3}\text{Sb}_{0.7}\text{F}_6]$  (100–295 K) and  $\beta$ - $[\text{XeF}_5][\text{As}_{0.5}\text{Sb}_{0.5}\text{F}_6]$  (295 K), both of which have a (3 + 1)-dimensional incommensurately modulated crystal structure (superspace group *Ama2(00\gamma)s0s*) [37]. At 150 K, the  $\alpha$ - $[\text{XeF}_5][\text{As}_{0.5}\text{Sb}_{0.5}\text{F}_6]$  salt is also orthorhombic, but not modulated (space group *Pca2<sub>1</sub>*) and with doubled *c*-axis (Table 8) [37]. In  $[\text{XeF}_5][\text{As}_{0.3}\text{Sb}_{0.7}\text{F}_6]$  and  $\beta$ - $[\text{XeF}_5][\text{As}_{0.5}\text{Sb}_{0.5}\text{F}_6]$  there are two crystallographically nonequivalent  $[\text{XeF}_5]^+$  cations and two crystallographically independent sites for pnictogen atoms, while in  $\alpha$ - $[\text{XeF}_5][\text{As}_{0.5}\text{Sb}_{0.5}\text{F}_6]$  there are four crystallographically nonequivalent  $[\text{XeF}_5]^+$  cations and four crystallographically different sites for pnictogen atoms.

All the compounds listed in Table 8 are structurally related, as indicated by the similar packing in their crystal structures (Figure 7). It is practically identical in the orthorhombic  $\text{XeF}_5\text{AsF}_6$ ,  $[\text{XeF}_5][\text{As}_{0.3}\text{Sb}_{0.7}\text{F}_6]$ , and  $\beta$ - $[\text{XeF}_5][\text{As}_{0.5}\text{Sb}_{0.5}\text{F}_6]$  and slightly different in  $\alpha$ - $[\text{XeF}_5][\text{As}_{0.5}\text{Sb}_{0.5}\text{F}_6]$  due to the different inclination of some  $\text{AF}_6$  (A = As, Sb) octahedra.

**Figure 7.** Packing of  $[\text{XeF}_5]^+$  cations and  $[\text{AF}_6]^-$  anions (A = As, Sb) in the crystal structures of (a) orthorhombic  $[\text{XeF}_5][\text{AsF}_6]$ ; (b)  $\alpha$ - $[\text{XeF}_5][\text{As}_{0.5}\text{Sb}_{0.5}\text{F}_6]$ ; (c) average structure of  $[\text{XeF}_5][\text{As}_{0.3}\text{Sb}_{0.7}\text{F}_6]$ . The last figure is reproduced from Ref. [37] and published under the terms and conditions of the Creative Commons Attribution 4.0 International License CC BY 4.0.

In the orthorhombic  $[\text{XeF}_5][\text{AsF}_6]$  [53] each  $[\text{Xe}(1)\text{F}_5]^+$  cation forms three shorter ( $<3$  Å) and one longer secondary contact (3.451 (7) Å) with the fluorine atoms of four  $\text{AsF}_6$  groups. The sum of the  $\text{Xe}\cdots\text{F}$  van der Waals radii is 3.63 Å [55]. The other  $[\text{Xe}(2)\text{F}_5]^+$  cation is also involved in four secondary interactions ( $<3$  Å), but only with three  $\text{AsF}_6$  groups. Each  $[\text{As}(1)\text{F}_6]^-$  anion interacts with four  $[\text{XeF}_5]^+$  cations and each  $[\text{As}(2)\text{F}_6]^-$  anion interacts with only three  $[\text{XeF}_5]^+$  cations (Figure 8).

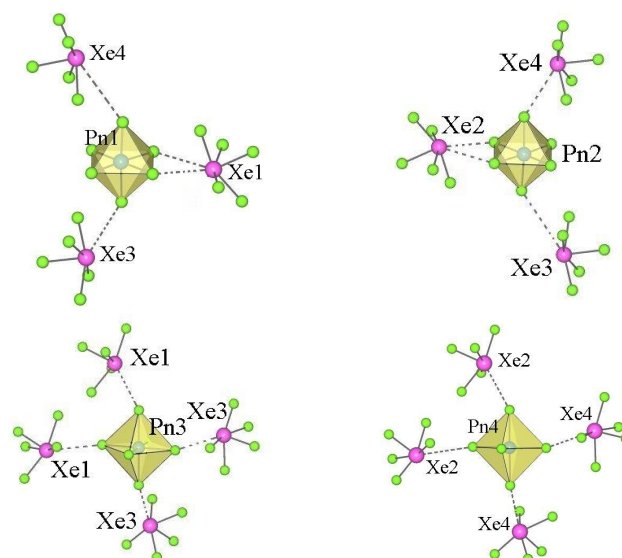

**Figure 8.** Secondary contacts between the  $[\text{XeF}_5]^+$  cations and the  $[\text{AsF}_6]^-$  anions in the crystal structure of orthorhombic  $[\text{XeF}_5][\text{AsF}_6]$  (type IV).

In  $\alpha$ - $[\text{XeF}_5][\text{As}_{0.5}\text{Sb}_{0.5}\text{F}_6]$  [37], the cations  $[\text{Xe}(1)\text{F}_5]^+$  and  $[\text{Xe}(2)\text{F}_5]^+$  each form four secondary contacts ( $<3 \text{ \AA}$ ) with the fluorine atoms of three  $\text{AF}_6$  groups ( $A = \text{As}, \text{Sb}$ ), while  $[\text{Xe}(3)\text{F}_5]^+$  and  $[\text{Xe}(4)\text{F}_5]^+$  have three shorter ( $<3 \text{ \AA}$ ) and one longer ( $3.437(7) \text{ \AA}$  and  $3.420(7) \text{ \AA}$ , respectively) contact with four  $\text{AF}_6$  groups (Figure 9). Each of the crystallographically unique  $[\text{A}(1)\text{F}_6]^-$  and  $[\text{A}(2)\text{F}_6]^-$  anions forms four interactions with three  $[\text{XeF}_5]^+$  cations, while the  $[\text{A}(3)\text{F}_6]^-$  and  $[\text{A}(4)\text{F}_6]^-$  anions form four interactions with four  $[\text{XeF}_5]^+$  cations, (Figure 10).

**Figure 9.** Secondary contacts between the  $[\text{XeF}_5]^+$  cations and the surrounding  $[\text{AF}_6]^-$  anions ( $A = \text{As}, \text{Sb}$ ) in the crystal structure of  $\alpha$ - $[\text{XeF}_5][\text{As}_{0.5}\text{Sb}_{0.5}\text{F}_6]$ .

**Figure 10.** Secondary contacts between the  $[AF_6]^-$  ( $A = As, Sb$ ) anions and the surrounding  $[XeF_5]^+$  cations in the crystal structure of  $\alpha$ - $[XeF_5][As_{0.5}Sb_{0.5}F_6]$ .

### 3.1.5. General Considerations for $XeF_5AF_6$ Salts ( $A = Nb, Ta, Ru, Rh, Os, Ir, Pt, Au, As, Sb$ )

Table 9 lists the effective ionic radii  $r(A^{5+})$  ( $A = Nb, Ta, Ru, Rh, Os, Ir, Pt, Au, As, Sb$ ) for coordination number six [56], the formula units (molecular) volumes  $V_{FU}$  of  $LiAF_6$ ,  $CsAF_6$ , and  $XeF_5AF_6$ , and the average A–F bond lengths in  $LiAF_6$  and  $XeF_5AF_6$ . The molecular volumes of  $LiAF_6$ ,  $CsAF_6$ , and  $XeF_5AF_6$  are shown in Figure 11. The crystal structures of  $LiAF_6$  ( $A = Nb, Ta, Ru, Rh, Os, Ir, Pt$ , and  $Au$ ) were determined by synchrotron X-ray powder diffraction at 299 K [57]. The crystal structures of  $LiAsF_6$  and  $LiSbF_6$  were determined by X-ray diffraction on powdered material and single crystals, respectively, at room temperature (RT) [58,59]. With the exception of  $CsAsF_6$  and  $CsSbF_6$ , whose complete crystal structures were determined on single crystals at RT, only unit cells determined at RT are available for the other  $CsAF_6$  salts [60]. The crystal structures of  $CsAF_6$  ( $A = Rh, Pt, Ir, Os$ , and  $Au$ ) were also determined on single crystals at 150 K [61]. The crystal structures of  $XeF_5AF_6$  ( $A = Nb, Ta, Ru, Rh, Ir, Pt, Au, As$  [37],  $Sb$  [25]) were determined at 150 K and some of them also at RT ( $A = As$  [41],  $Au$  [39],  $Pt$  [24],  $Ru$  [38],  $Sb$  [37],  $Nb$  [30]).

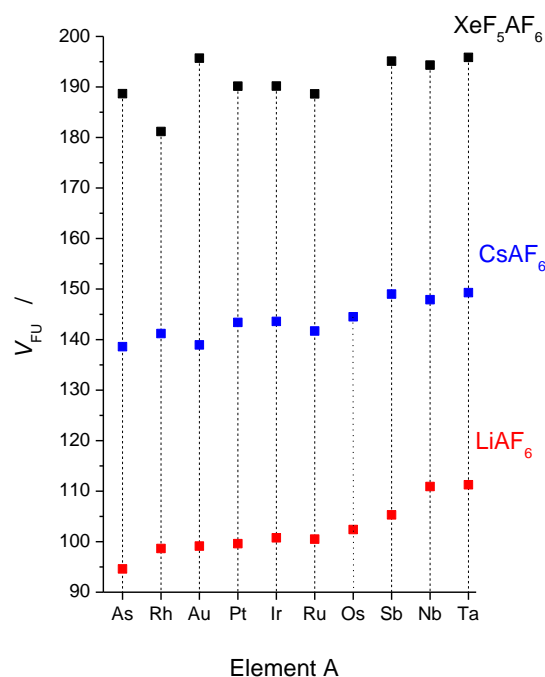

**Table 9.** Effective ionic radii  $r(A^{5+})$  ( $A = Nb, Ta, Ru, Rh, Os, Ir, Pt, Au, As, Sb$ ) for coordination number six (Å), formula unit (molecular) volumes  $V_{FU}$  (Å<sup>3</sup>) of  $LiAF_6$ ,  $CsAF_6$ , and  $XeF_5AF_6$ , and average A–F bond lengths  $d_{av}[A-F]$  (Å) in  $LiAF_6$  and  $XeF_5AF_6$ .

<sup>a</sup> Ref. [56]. <sup>b</sup> Room temperature (RT); Ref. [58]. <sup>c</sup> 299 K; Ref. [57]. <sup>d</sup> RT; Ref. [59]. <sup>e</sup> RT; Ref. [60]. <sup>f</sup> 150 K; Ref. [61]. <sup>g</sup> 285 K for Ir salt (this work); others RT (Refs. [24,30,37–39,41]). <sup>h</sup> This work (150 K) except  $XeF_5AsF_6$  (150 K) [37] and  $XeF_5SbF_6$  (150 K) [25].

Although the formula unit volumes  $V_{FU}$  of the  $\text{LiAF}_6$  and  $\text{CsAF}_6$  salts (Figure 11) show a similar trend, this is not the case for the  $\text{XeF}_5\text{AF}_6$  salts, with the  $V_{FU}$  of  $\text{XeF}_5\text{RhF}_6$  and  $\text{XeF}_5\text{AuF}_6$  being particularly prominent. For  $\text{LiAF}_6$  and  $\text{CsAF}_6$ , the  $V_{FU}$  are smallest for the As, Rh, and Au salts and largest for the Sb, Nb, and Ta salts. For the  $[\text{XeF}_5]^+$  salts, the  $V_{FU}$  of  $\text{XeF}_5\text{AuF}_6$  is almost identical to the  $V_{FU}$  of  $\text{XeF}_5\text{TaF}_6$ , while  $\text{XeF}_5\text{RhF}_6$  has the smallest value  $V_{FU}$  of all  $\text{XeF}_5\text{AF}_6$  salts (Table 9, Figure 11).

**Figure 11.** Formula unit volumes of  $\text{LiAF}_6$  (for  $A = \text{Rh}, \text{Au}, \text{Pt}, \text{Ir}, \text{Ru}, \text{Os}, \text{Nb}, \text{Ta}$  at 299 K and for  $A = \text{As}, \text{Sb}$  at room temperature),  $\text{CsAF}_6$  (all data at room temperature), and  $\text{XeF}_5\text{AF}_6$  salts (all data at 150 K).

### 3.2. Crystal Structures of $\text{XeF}_5\text{A}_2\text{F}_{11}$ ( $A = \text{Nb}, \text{Ta}, \text{Sb}$ )

In the  $\text{XeF}_6\text{-AF}_5$  ( $A = \text{Nb}, \text{Ta}$ ) system, only the salts  $\text{XeF}_5\text{AF}_6$  and  $\text{Xe}_2\text{F}_{11}\text{AF}_6$  have been known so far [30,62,63]. The salts  $\text{XeF}_5\text{Nb}_2\text{F}_{11}$  and  $\text{XeF}_5\text{Ta}_2\text{F}_{11}$  were prepared for the first time in this study. As in the case of  $\text{XeF}_5\text{Sb}_2\text{F}_{11}$  [25] (Figure 12) the crystal structures of  $\text{XeF}_5\text{A}_2\text{F}_{11}$  ( $A = \text{Nb}, \text{Ta}$ ) consist of discrete  $[\text{XeF}_5]^+$  cations and dimeric  $[\text{A}_2\text{F}_{11}]^-$  anions interacting through secondary fluorine bridge  $\text{Xe}\cdots\text{F}-\text{A}$  contacts (Figures 13 and 14). Each crystal structure of the  $\text{XeF}_5\text{A}_2\text{F}_{11}$  salts ( $A = \text{Sb}, \text{Nb}, \text{Ta}$ ) represents a unique example (Tables 2 and 5).

**Figure 12.** Secondary contacts between the  $[\text{XeF}_5]^+$  cations and the  $[\text{Sb}_2\text{F}_{11}]^-$  anions in the crystal structure of  $\text{XeF}_5\text{Sb}_2\text{F}_{11}$ .

**Figure 13.** Secondary contacts between the  $[\text{XeF}_5]^+$  cations and the  $[\text{Nb}_2\text{F}_{11}]^-$  anions in the crystal structure of  $\text{XeF}_5\text{Nb}_2\text{F}_{11}$ .

**Figure 14.** Secondary contacts between the  $[\text{XeF}_5]^+$  cations and the  $[\text{Ta}_2\text{F}_{11}]^-$  anions in the crystal structure of  $\text{XeF}_5\text{Ta}_2\text{F}_{11}$ .

In  $\text{XeF}_5\text{Nb}_2\text{F}_{11}$ , each  $[\text{XeF}_5]^+$  cation forms three secondary contacts with the fluorine atoms of two  $\text{Nb}_2\text{F}_{11}$  groups, whereas in  $\text{XeF}_5\text{Sb}_2\text{F}_{11}$  and  $\text{XeF}_5\text{Ta}_2\text{F}_{11}$ , each  $[\text{A}_2\text{F}_{11}]^-$  anion ( $A = \text{Nb}, \text{Ta}$ ) participates in four secondary contacts with three different  $\text{A}_2\text{F}_{11}$  dimers (Figures 12–14). In all three salts, the  $\text{Xe}-\text{F}_{\text{ax}}$  bonds are shorter than the other four  $\text{Xe}-\text{F}_{\text{eq}}$  distances (Table 5). The  $\text{A}-\text{F}_{\text{b}}-\text{A}$  bridge (Table 5) in the dimeric  $[\text{A}_2\text{F}_{11}]^-$  anion ( $A = \text{Sb}, \text{Nb}, \text{Ta}$ ) is not linear as in  $[\text{A}_2\text{F}_{11}]^-$  ( $M = \text{Nb}, \text{Ta}$ ) salts of protonated 1,3-dimethoxybenzene but bent as in many other examples [64]. In  $\text{XeF}_5\text{Sb}_2\text{F}_{11}$ , the four  $\text{F}_{\text{eq}}$  atoms of the  $\text{Sb}(1)\text{F}_6$  unit are in staggered position in respect to the four  $\text{F}_{\text{eq}}$  of the  $\text{Sb}(2)\text{F}_6$  group with a torsion angle of  $\sim 37.5^\circ$ , while in the corresponding Nb and Ta salts they are almost in an eclipsed position.

### 3.3. Crystal Structure of $\text{XeF}_5\text{Ni}(\text{AsF}_6)_3$

The crystal structure of  $\text{XeF}_5\text{Ni}(\text{AsF}_6)_3$  (Figure 15) is isotypical to the crystal structure of  $\text{XeF}_5\text{Ni}(\text{SbF}_6)_3$  [35]. The cation  $\text{Ni}^{2+}$  is coordinated by six fluorine atoms provided by six octahedral anions  $[\text{AsF}_6]^-$  forming almost regular  $\text{NiF}_6$  octahedra. The  $\text{Ni}-\text{F}$  bond lengths in both salts are virtually identical (Table 6). They range from 1.989 (1) to 2.013 (1) Å. Due to the sharing of fluorine atoms, the  $\text{NiF}_6$  and  $\text{AsF}_6$  octahedra are connected to form a three-dimensional framework. The  $[\text{XeF}_5]^+$  cations are located inside the cavities. The geometry of the  $[\text{XeF}_5]^+$  cations is almost identical in both Ni salts (Table 5).

**Figure 15.** Part of the crystal structure of  $\text{XeF}_5\text{Ni}(\text{AsF}_6)_3$ .

#### 3.4. Crystal Structures of the Salts $(\text{Xe}_2\text{F}_{11})_2(\text{NiF}_6)_2$ and $\text{Ni}(\text{XeF}_2)_2(\text{IrF}_6)_2$

The crystal structure of  $(\text{Xe}_2\text{F}_{11})_2(\text{NiF}_6)_2$  determined at 150 K is the same as that at room temperature [40], which means that there is no phase transition in the 150–296 K range.

It has been reported that the reaction between  $\text{M}^{n+}(\text{AF}_6)_n^-$  and  $\text{XeF}_2$  in anhydrous aHF (aHF) leads to coordination compounds  $[\text{M}^{n+}(\text{XeF}_2)_p](\text{AF}_6)_n^-$  (where  $\text{XeF}_2$  is coordinated to a metal cation  $\text{M}^{n+}$ ) only when the Lewis acidity of  $\text{M}^{n+}$  is not high enough to withdraw  $\text{F}^-$  ions from  $\text{XeF}_2$  to form  $\text{MF}_n$  and  $\text{Xe}_2\text{F}_3^+\text{AF}_6^-$  [65]. Since the reaction between  $\text{Ni}(\text{AsF}_6)_2$  and  $\text{XeF}_2$  in aHF gave  $\text{NiF}_2$  and  $\text{Xe}_2\text{F}_3\text{AsF}_6$ , the preparation of  $[\text{Ni}(\text{XeF}_2)_2](\text{IrF}_6)_2$  was a small surprise.

The crystal structure of  $[\text{Ni}(\text{XeF}_2)_2](\text{IrF}_6)_2$  is isotypical to the crystal structure of  $[\text{Cu}(\text{XeF}_2)_2](\text{SbF}_6)_2$  [54]. In both structures, adjacent  $[\text{M}(\text{XeF}_2)_2]^{2+}$  units are connected via two  $[\text{AF}_6]^-$  units with bridging fluorine atoms in the cis position to form infinite chains that are parallel to the  $x$ -axis (Figure 16). These chains are interconnected by weak  $\text{F}_2\text{Xe}\cdots\text{F}-\text{AF}_5$  contacts and form a three-dimensional network.

**Figure 16.** Part of the crystal structure of  $[\text{Ni}(\text{XeF}_2)_2](\text{IrF}_6)_2$ .

The metal cation  $\text{Ni}^{2+}$  is sixfold coordinated by fluorine atoms of two  $\text{XeF}_2$  ligands and four  $[\text{IrF}_6]^-$  anions. In  $[\text{Cu}(\text{XeF}_2)_2](\text{SbF}_6)_2$ , the  $\text{Cu}^{2+}$  cation is coordinated by two  $\text{XeF}_2$  molecules ( $\text{Cu}-\text{F} = 2 \times 1.857(5) \text{ \AA}$ ) and four fluorine atoms provided by four  $[\text{SbF}_6]^-$  units with two shorter and two longer  $\text{Cu}-\text{F}$  bonds ( $2 \times 2.090(5) \text{ \AA}$  and  $2 \times 2.123(5) \text{ \AA}$ ) [54]. In contrast, the  $\text{Ni}-\text{F}(\text{Ir})$  bonds in the  $[\text{Ni}(\text{XeF}_2)_2](\text{IrF}_6)_2$  salt are almost the same length ( $2 \times 2.016(9) \text{ \AA}$  and  $2 \times 2.023(7) \text{ \AA}$ ). The  $\text{Ni}-\text{F}(\text{XeF}_2)$  bonds are much longer ( $2 \times 1.938(6) \text{ \AA}$ ) than in the  $[\text{Cu}(\text{XeF}_2)_2](\text{SbF}_6)_2$  salt ( $2 \times 1.857(5) \text{ \AA}$ ), indicating a weaker  $\text{M}^{2+}-\text{FXeF}$  interaction in the Ni salt. Consequently,  $\text{Xe}-\text{F}_b$  ( $\text{F}_b =$  bridging F atom) is shorter ( $2.078(6) \text{ \AA}$ ) in the Ni salt than in the Cu salt ( $2.102(5) \text{ \AA}$ ) and the opposite is true for  $\text{Xe}-\text{F}_t$  bonds [ $\text{F}_t =$  terminal fluorine atom;  $1.920(7) \text{ \AA}$  (Ni salt) and  $1.906(5) \text{ \AA}$  (Cu salt)].

## 4. Materials and Methods

CAUTION: Anhydrous HF and some fluorides are highly toxic and must be handled under a well-ventilated hood, and protective clothing must be worn at all times!

### 4.1. Apparatus, Techniques, and Reagents

The handling of volatile (anhydrous HF, F<sub>2</sub>, AsF<sub>5</sub>, BF<sub>3</sub>) and nonvolatile materials and the type of the reaction and crystallization vessels have already been reported [35,47,66]. Metallic Re powder (Alfa Aesar, Haverhill, MA, USA, 99.99%), Ru sponge (Alfa Aesar, 99.95%), Rh sponge (BDH, 99.9%), Os powder (Alfa Aesar, 99.8%), Ir sponge (Alfa Aesar, 99.95%), Pt powder (Aldrich, St. Louis, MO, USA, 99.9%), elemental F<sub>2</sub> (Solvay Fluor and Derivate GmbH, Hannover, Germany 99.98%), CrF<sub>3</sub> (Messer Griesheim, Bad Soden, Germany, 99.9%), and BF<sub>3</sub> (Union Carbide Austria, GmbH, 99.5%) were used as supplied. Anhydrous HF (Linde AG, Pullach, Germany, 99.995%) was treated with K<sub>2</sub>NiF<sub>6</sub> (Advance Research Chemicals Inc, Catoosa, OK, USA, 99.9%) for several hours before use. NiF<sub>2</sub> (Alfa Products, Bedford Park, IL, USA, 99.5%) and CuF<sub>2</sub> (Aldrich, 98%) were treated with elemental F<sub>2</sub> at 220 °C for several hours before use. NbF<sub>5</sub> (Alfa Aesar, 99%) and TaF<sub>5</sub> (Alfa Aesar, 99.9%) were sublimed before use. AuF<sub>3</sub> [66], XeF<sub>2</sub> [67], AsF<sub>5</sub> [68], XeF<sub>5</sub>SbF<sub>6</sub> [34], Sn(SbF<sub>6</sub>)<sub>2</sub> [69,70], Pb(SbF<sub>6</sub>)<sub>2</sub> [69,70], and Zn(SbF<sub>6</sub>)<sub>2</sub> [69,70] were synthesized as described previously.

Raman spectra were recorded at room temperature using a Renishaw Raman Imaging Microscope System 1000 or a Horiba Jobin Yvon LabRam-HR spectrometer [66].

### 4.2. Attempted Preparation of XeF<sub>5</sub>M(AF<sub>6</sub>)<sub>3</sub> (M = Cu, Ni; A = Cr, Nb, Ta, Ru, Rh, Re, Os, Ir, Pt, Au, As), XeF<sub>5</sub>M(SbF<sub>6</sub>)<sub>3</sub> (M = Sn, Pb), and XeF<sub>5</sub>M(BF<sub>4</sub>)<sub>x</sub>(SbF<sub>6</sub>)<sub>3-x</sub> (x = 1, 2, 3; M = Co, Mn, Ni, Zn)

The solid starting reagents were loaded into reaction vessels in a dry box (Table S1). The solvent HF and optionally BF<sub>3</sub>, AsF<sub>5</sub>, and SbF<sub>5</sub> were condensed at 77 K to solid reagents, and the reaction vessel was warmed to ambient temperature. Fluorine was slowly added to the reaction vessel at room temperature. A medium-pressure mercury lamp (Hg arc lamp, 450 W, Ace Glass, Vineland, NJ, USA) was used as the UV source. After several days of intensive stirring at room temperature, the volatiles were pumped off and the Raman spectra of the obtained solids were recorded (Figures S1–S11).

For crystallization, the clear supernatant, which contained no visible sediment, was decanted into the side arm of the crystallization vessel, which consisted of two tubes made of fluoropolymer. Evaporation of the solvent from the side arm was achieved by maintaining a temperature gradient of about 10–20 °C between the two tubes for several weeks. Slow distillation of aHF resulted in crystal growth.

Crystals were immersed in perfluorodecalin (melting point 263 K) in a dry box, selected under the microscope, and mounted on the goniometer head of the diffractometer in a cold nitrogen stream (265–273 K). Some of them were sealed in quartz capillaries used to record Raman spectra at several random positions (Figures S1–S11).

### 4.3. Crystal Structure Determination

Single-crystal X-ray diffraction data of reported crystal structures were acquired at 150 K (for XeF<sub>5</sub>IrF<sub>6</sub> also at 285 K) with a Gemini A diffractometer equipped with an Atlas CCD detector using graphite monochromated MoK $\alpha$  radiation. The data were processed using the CrysAlisPro software suite program package [71]. Analytical absorption corrections were applied to all data sets. All structures were solved using the dual-space algorithm of the program SHELXT [72] implemented in the Olex crystallographic software [73]. Structure refinement for all structures was performed using the software SHELXL-2014 [74]. The crystals of the Ni(XeF<sub>2</sub>)<sub>2</sub>(IrF<sub>6</sub>)<sub>2</sub> salt showed reproducible pseudo-merohedral twinning. This problem was solved at the data processing stage, and final refinement was performed using reflections from the main domain. The figures were created using the software Balls and Sticks [75]. The compound XeF<sub>5</sub>Nb<sub>2</sub>F<sub>11</sub> crystallizes in the acentric space group *P*2<sub>1</sub>.

The very-close-to-zero value of the Flack's parameter ( $-0.031(11)$ ) confirms the correctness of the absolute structure.

The supplementary crystallographic data for this work are provided free of charge by the joint Cambridge Crystallographic Data Centre and the Fachinformationszentrum Karlsruhe Access Structures service [www.ccdc.cam.ac.uk/structures](http://www.ccdc.cam.ac.uk/structures) (accessed on 10 March 2023): CSD-2246135 [(Xe<sub>2</sub>F<sub>11</sub>)<sub>2</sub>NiF<sub>6</sub>], CSD-2246136 [Ni(XeF<sub>2</sub>)<sub>2</sub>(IrF<sub>6</sub>)<sub>2</sub>], CSD-2246137 [XeF<sub>5</sub>AuF<sub>6</sub>], CSD-2246138 [XeF<sub>5</sub>IrF<sub>6</sub>, 150 K], CSD-2246139 [XeF<sub>5</sub>Nb<sub>2</sub>F<sub>11</sub>], CSD-2246140 [XeF<sub>5</sub>PtF<sub>6</sub>], CSD-2246141 [XeF<sub>5</sub>RuF<sub>6</sub>], CSD-2246142 [XeF<sub>5</sub>IrF<sub>6</sub>, 280 K], CSD-2246143 [XeF<sub>5</sub>Ta<sub>2</sub>F<sub>11</sub>], CSD-2246144 [XeF<sub>5</sub>NbF<sub>6</sub>], CSD-2246145 [XeF<sub>5</sub>Ni(AsF<sub>6</sub>)<sub>3</sub>], CSD-2246146 [XeF<sub>5</sub>TaF<sub>6</sub>], CSD-2246147 [XeF<sub>5</sub>RhF<sub>6</sub>].

## 5. Conclusions

Although the experiments to prepare XeF<sub>5</sub>M(BF<sub>4</sub>)<sub>x</sub>(SbF<sub>6</sub>)<sub>3-x</sub> ( $x = 1, 2, 3$ ; M = Co, Mn, Ni, Zn), XeF<sub>5</sub>M(SbF<sub>6</sub>)<sub>3</sub> (M = Sn, Pb), and XeF<sub>5</sub>M(AF<sub>6</sub>)<sub>3</sub> salts (M = Cu, Ni; A = Cr, Nb, Ta, Ru, Rh, Re, Os, Ir, Pt, Au, As) were successful only in the preparation of XeF<sub>5</sub>Ni(AsF<sub>6</sub>)<sub>3</sub>, further valuable results were obtained:

- In view of the successful preparation of XeF<sub>5</sub>Ni(AsF<sub>6</sub>)<sub>3</sub>, we assume that it is reasonable to attempt the preparation of other compounds with other M<sup>2+</sup> cations (M = Mg, Fe, Co, Zn, etc.).
- Crystal structure determination of XeF<sub>5</sub>RhF<sub>6</sub> reveals a new type of structure. Together with the crystal structures of XeF<sub>5</sub>TaF<sub>6</sub> and XeF<sub>5</sub>IrF<sub>6</sub>, which were determined for the first time, and the redetermined crystal structures of XeF<sub>5</sub>NbF<sub>6</sub>, XeF<sub>5</sub>PtF<sub>6</sub>, XeF<sub>5</sub>RuF<sub>6</sub>, and XeF<sub>5</sub>AuF<sub>6</sub>, they contribute to the understanding of the possible crystal phases in the family of XeF<sub>5</sub>AF<sub>5</sub> salts.
- The crystal structures of the XeF<sub>5</sub>Nb<sub>2</sub>F<sub>11</sub> and XeF<sub>5</sub>Ta<sub>2</sub>F<sub>11</sub> salts were determined. These compounds were previously unknown, and for the XeF<sub>5</sub>A<sub>2</sub>F<sub>11</sub> salts, only the crystal structure of XeF<sub>5</sub>Sb<sub>2</sub>F<sub>11</sub> [25] was known. These three [A<sub>2</sub>F<sub>11</sub>]<sup>−</sup> salts are not isotypic and each of them represents a unique structural type.
- The crystal structure of XeF<sub>5</sub>IrF<sub>6</sub> determined at 150 K and at room temperature is identical. The crystal structures of the salts XeF<sub>5</sub>NbF<sub>6</sub>, XeF<sub>5</sub>PtF<sub>6</sub>, XeF<sub>5</sub>RuF<sub>6</sub>, XeF<sub>5</sub>AuF<sub>6</sub>, XeF<sub>5</sub>AsF<sub>6</sub> [37], and (Xe<sub>2</sub>F<sub>11</sub>)<sub>2</sub>NiF<sub>6</sub> redetermined at 150 K are also identical to those determined at room temperature, indicating that there is no phase transition in the range from 150 K to 298 K.
- All the new data on the XeF<sub>5</sub>AF<sub>6</sub> and XeF<sub>5</sub>A<sub>2</sub>F<sub>11</sub> salts help to fill the gaps in our knowledge of the XeF<sub>6</sub>-A<sup>V</sup>F<sub>5</sub> system (Table 10).
- The preparation of Ni(XeF<sub>2</sub>)<sub>2</sub>(IrF<sub>6</sub>)<sub>2</sub> has shown that it is worthwhile to try the preparation of some other [M<sup>n+</sup>(XeF<sub>2</sub>)<sub>p</sub>](AF<sub>6</sub>)<sub>n</sub><sup>−</sup> salts (A = Rh, Ru, Os, Ir, Pt, Au, Nb, Ta) where attempts to stabilize such salts with [AF<sub>6</sub>]<sup>−</sup> (A = As, Sb) have failed.

**Table 10.** List of known xenon(VI) fluoridometallates including the determined crystal structures (letters in bold). Crystal structures reported in this work are highlighted in green.
