Figure S1. FTIR spectra for DP401 lignosulfonate before (a) and after treatment with laccase (b), showing significant changes after lignin oxidation by the enzyme such as: i) decrease of the intensity of the band around 1220 cm⁻¹ corresponding to S=O groups and of the distinct band at 652 cm⁻¹ assigned to stretching vibration of sulfonic groups; ii) replacement of the lignin's characteristic bands between 1600- 1425 cm⁻¹ (assigned to C=C skeletal vibrations, aromatic ring vibrations and C-H deformation), by two large peaks at this region, the new peak at 1685 cm⁻¹ corresponds to unconjugated carbonyl-carboxyl stretching; iii) changes in 1331 cm⁻¹ band reported for syringyl rings (predominant in hardwood lignin) ; iv) increases in intensity of bands appeared at 1138 and 802 cm⁻¹, associated to CH deformations (in plane and out of the plane, respectively); and v) new peak detected at 950 cm⁻¹ related to the C-C stretch of aliphatic chains obtained after oxidation by laccase.
