

## Supplementary data

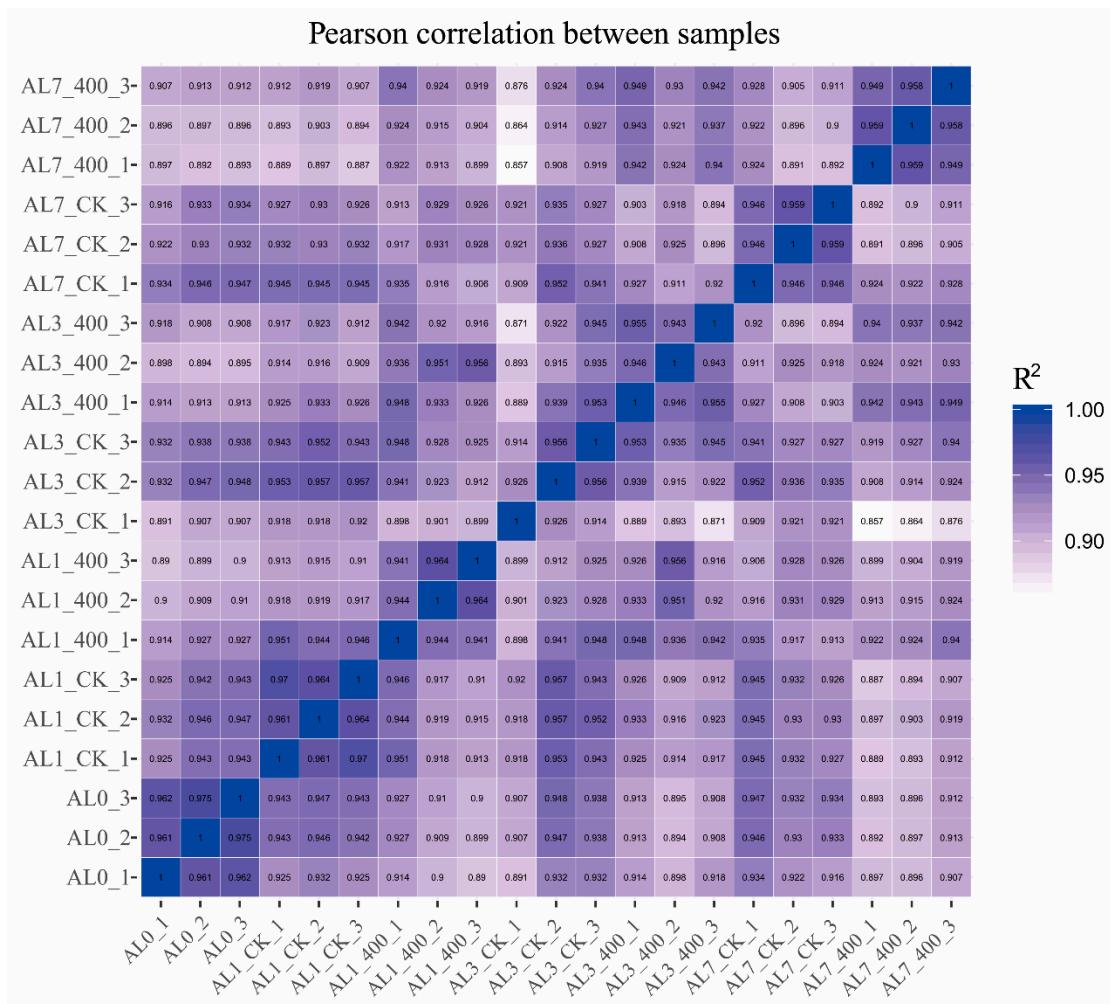

Figure Supplementary 1. Pearson correlation between samples. Taking the square of the Pearson correlation coefficient ( $R^2$ ) greater than 0.92 (under ideal sampling and experimental conditions), in specific project operations,  $R^2$  is required to be at least greater than 0.8 as the test index for the correlation of gene expression levels between samples, thereby verifying the reliability of the experiment and strictness of sample selection. The closer the correlation coefficient is to 1, the higher the similarity of the expression patterns between samples. The abscissa and ordinate are the log10 (FPKM+1) of the compared samples, and the ordinate is the sample type.

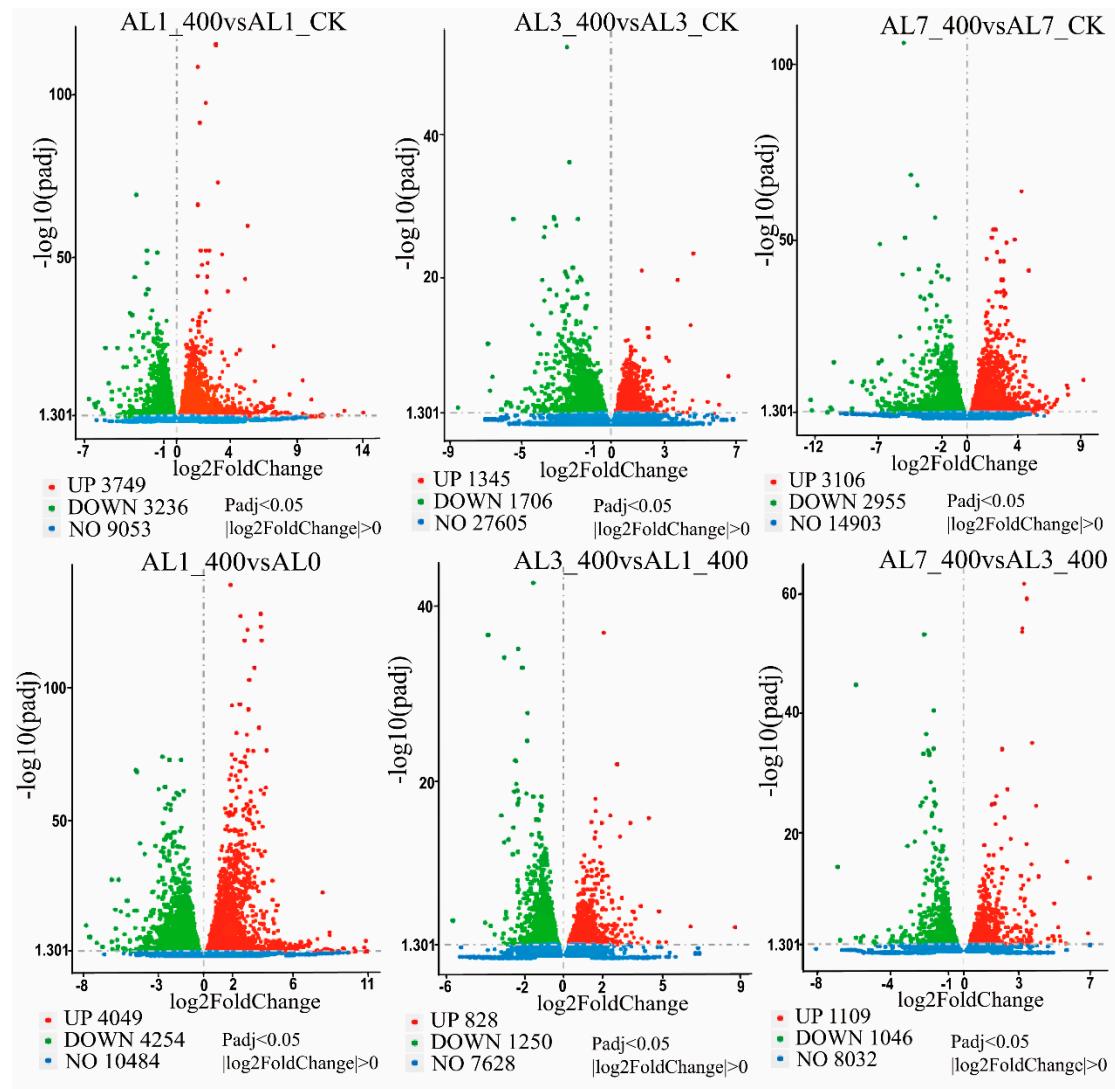

Figure Supplementary 2. Volcanic map of differentially expressed gene (DEGs). The distribution of differentially expressed genes (DEGs) in different combinations of roots of *Euphorbia angustifolia* at different time (0 d, 1 d, 3 d, 7 d) of treatment group (AL1\_400, AL3\_400, AL7\_400) and control group (AL0, AL1\_CK, AL3\_CK, AL7\_CK). The Abscissa represents the multiple change of gene expression in different samples; the ordinate indicates the statistically significant difference in gene expression; the red dot in the picture indicates the up-regulated gene with significant difference in expression, and the green dot represents the down-regulated gene with significant difference in expression. (FDR  $< 0.05$ ,  $| \log_{2}(\text{FoldChange}) | > 0$ ).

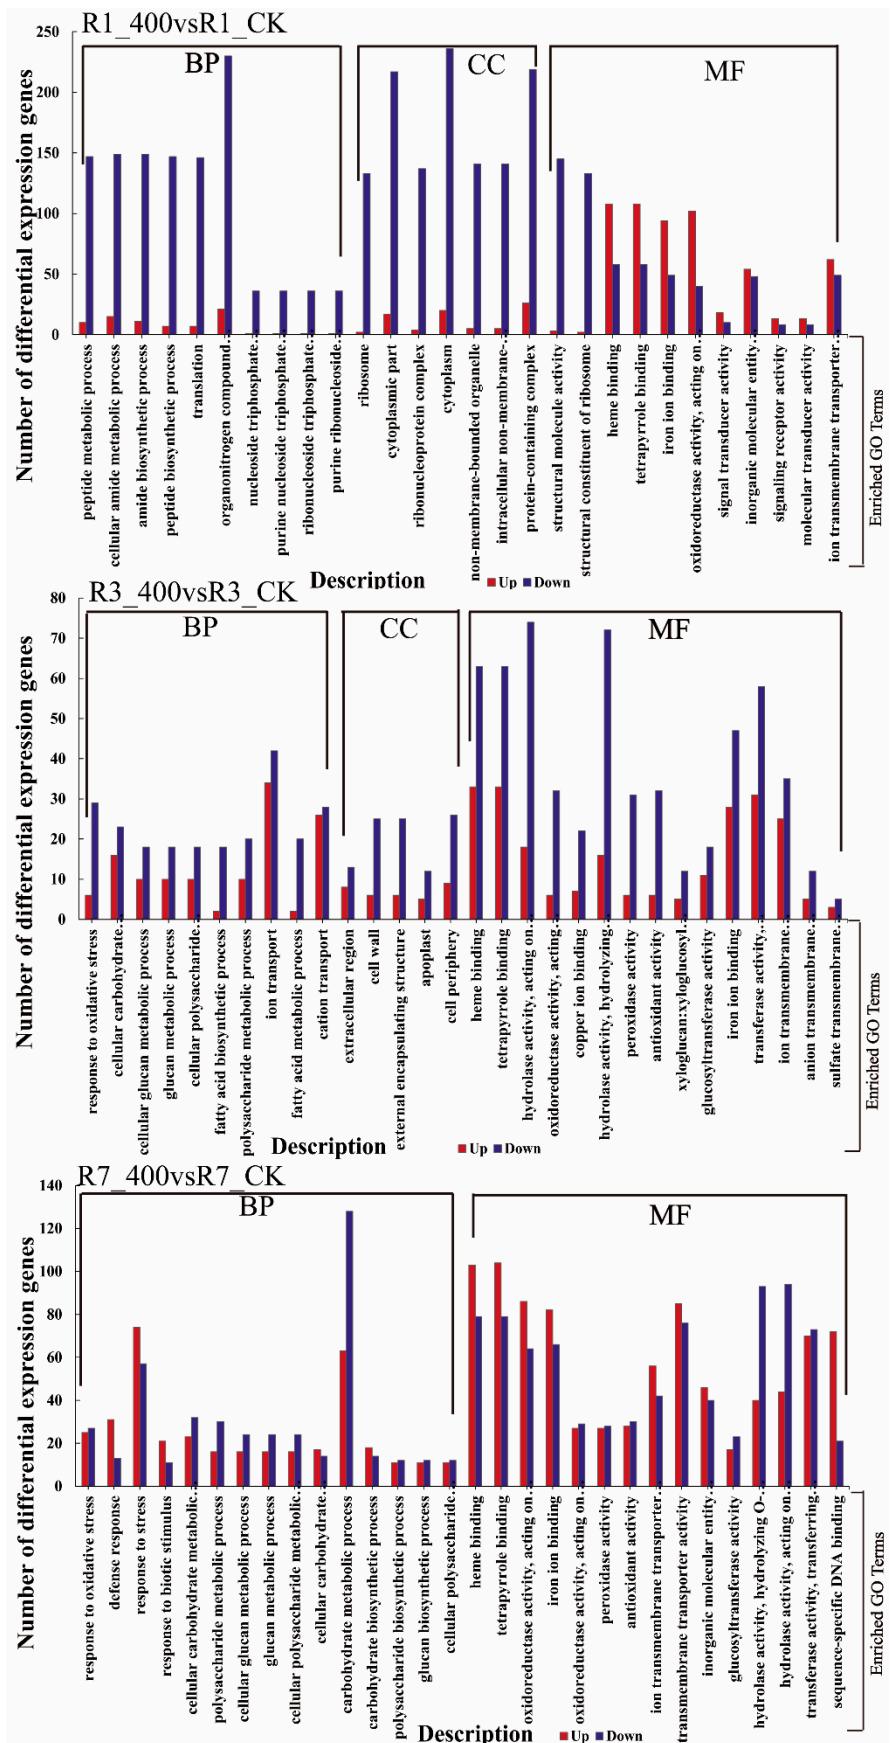

Figure Supplementary 3. GO enrichment of three comparative combinations of aluminum stress in different periods. The DEGs in the first 10 pathways that were significantly enriched in different periods of aluminum stress were screened, and all DEGs in less than 10 pathways were displayed. The abscissa represents the different GO term enriched genes, the ordinate represents the number of

DEGs. The red bar represents the up-regulated genes, the blue bar represents the down-regulated genes. BP represents DEGs enriched in biological processes, MF represents DEGs enriched in molecular functions, and CC represents DEGs enriched in cellular component.

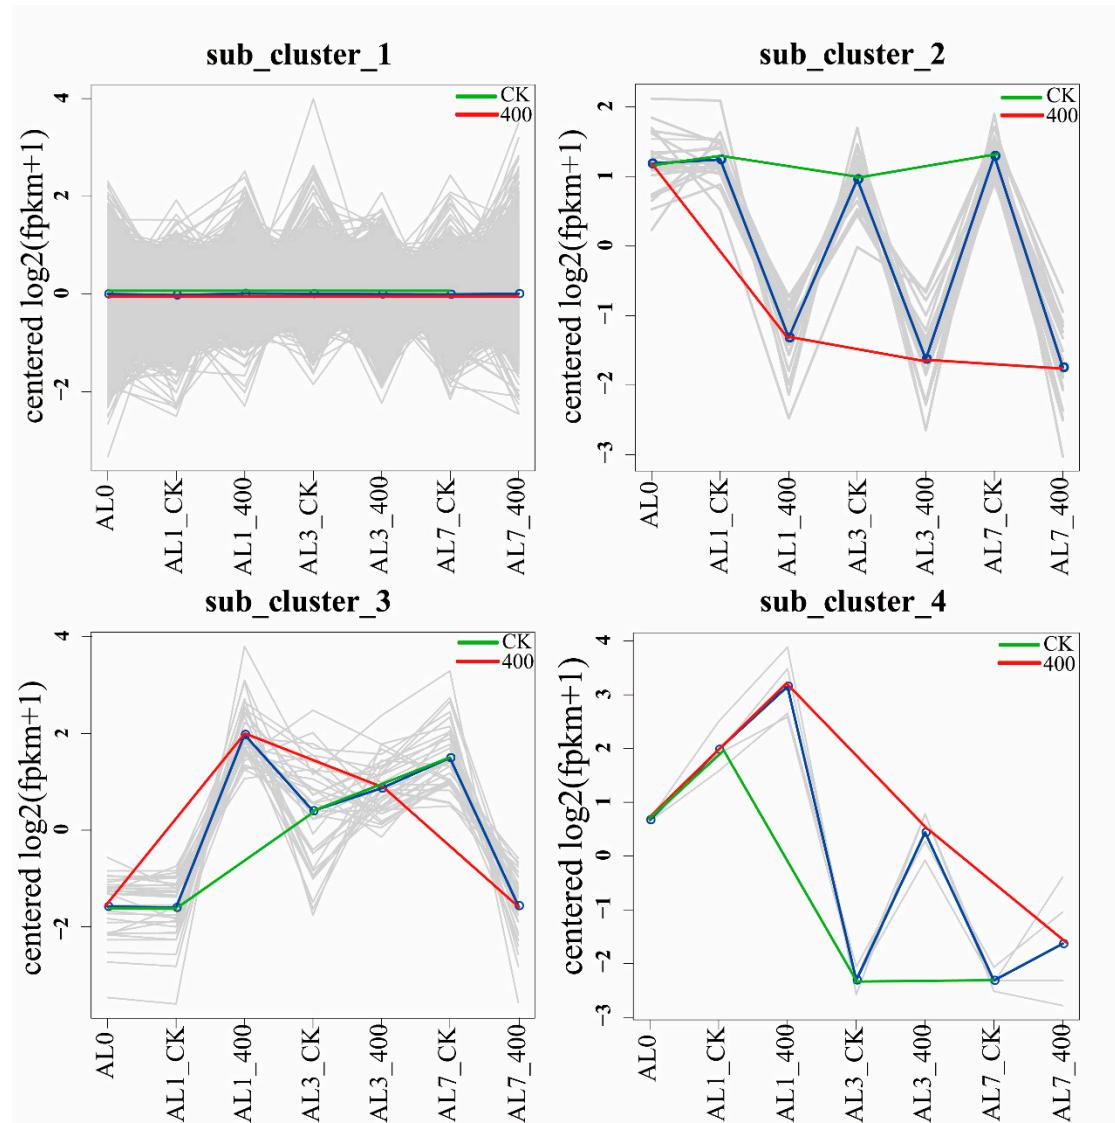

Figure Supplementary 4. Trend clustering of DEGs. The green lines indicate the trend of gene clustering in the control group; the red lines indicate the trend of gene clustering in the treatment group; the blue line shows the average relative expression of all genes in this cluster under different experimental conditions; The gray lines in each subgraph represent a line chart of the relative expression of genes in a cluster under different experimental conditions.

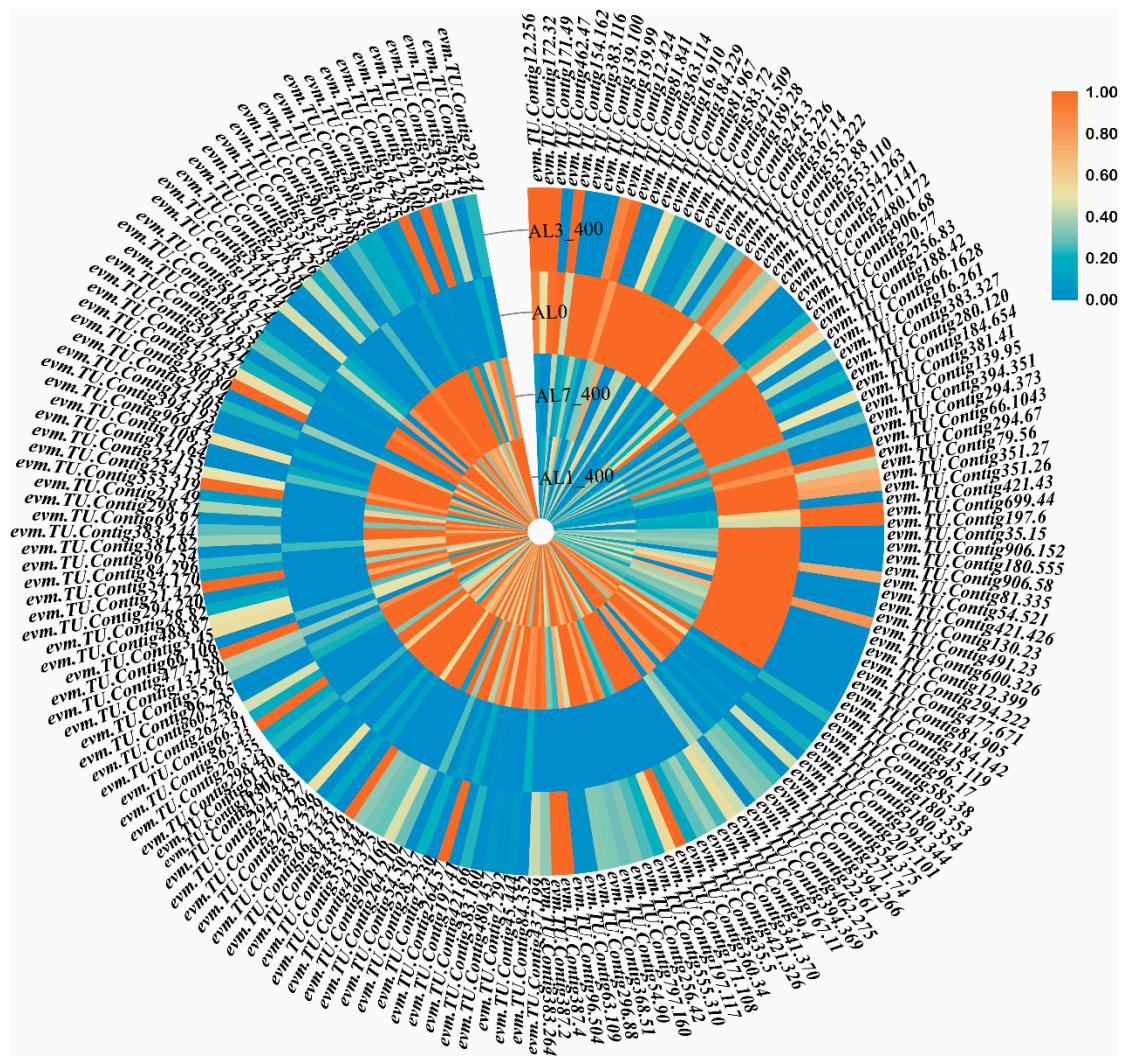

Table Supplementary 1. Quality evaluation of sequencing data

The number of reads in the raw data; clean\_reads: the number of reads filtered from the original data; clean\_bases: the number of bases filtered from the original data; error\_rate: error rate of overall data sequencing; Q20: the percentage of bases with a Phred value greater than 20 to the total base; Q30: the percentage of

bases with a Phred value greater than 30 in the total base; GC content: the percentage of G and C in four bases in clean reads.

Total\_reads : clean reads number of sequencing data after quality control;

total\_map : compare the number and percentage of reads on the genome;

multi\_map: the number and percentage of reads mapped to multiple locations of

the reference genome; unique\_map: the number and percentage of reads compared

to the unique location of the reference genome; read1\_map: the number and

percentage of read1 compared to the reference genome; read2\_map: the number

and percentage of read2 compared to the reference genome.

The FDR ( $\text{FDR} < 0.05$ ) and the fold change ( $|\log_2(\text{FoldChange})| > 1$ ) were used as indicators to screen the differentially expressed genes between aluminum stress induced group and control group at different time. A negative value of  $\log_2\text{FoldChange}$  indicates that the gene expression is down-regulated, while a positive value indicates that the gene expression is up-regulated.

Table Supplementary 5. New DEGs and unnamed DEGs

The FDR (FDR < 0.05) and the fold change ( $|\log_2(\text{FoldChange})| > 1$ ) were used as indicators to screen the differentially expressed genes after aluminum stress in contrast to control conditions. A negative value of  $\log_2\text{FoldChange}$  indicates that the gene expression is down-regulated, while a positive value indicates that the gene expression is up-regulated.
