Table S1. Gradient elution of the mobile phase for the synthetic compounds using HPLC.

The mobile phase consisted of Solution A (0.1% acetic acid in water) and Solvent B (acetonitrile), with gradient elution employed throughout the analysis. The flow rate was set at 2.0 mL/min.

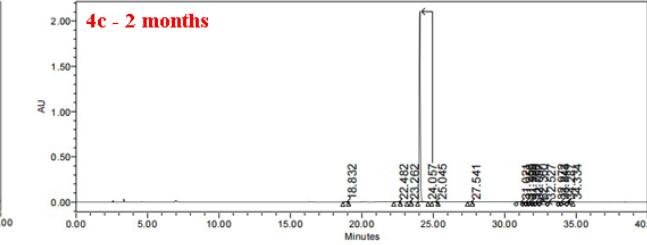

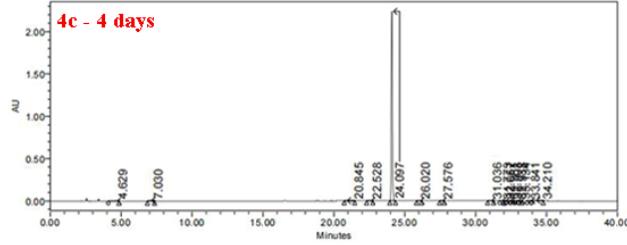

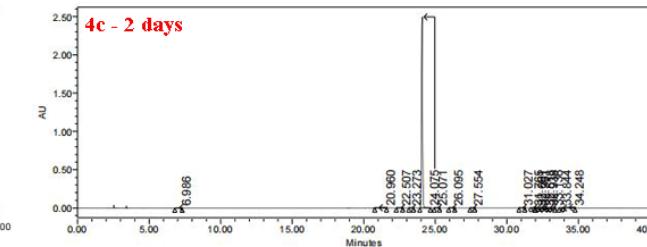

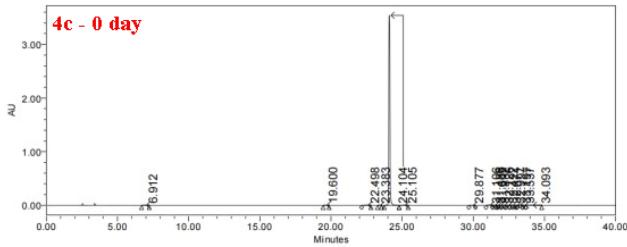

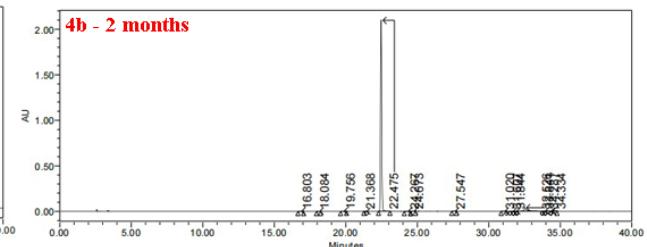

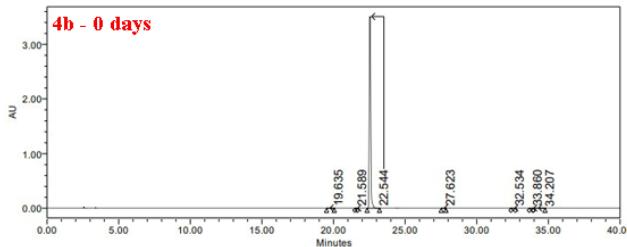

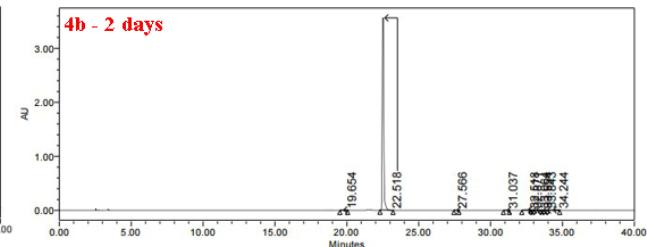

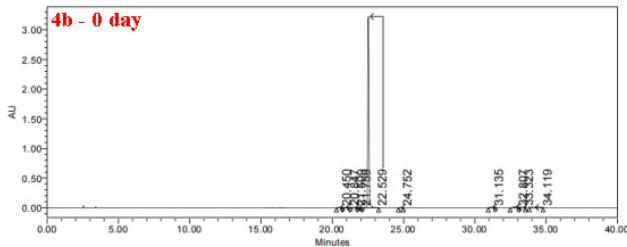

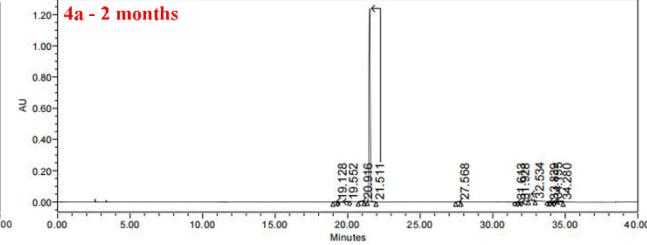

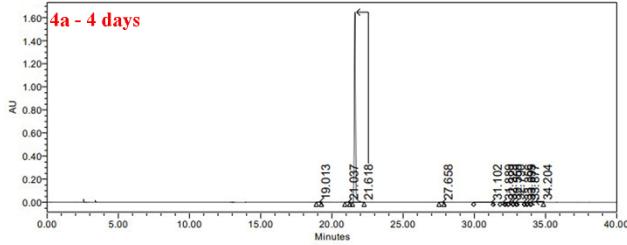

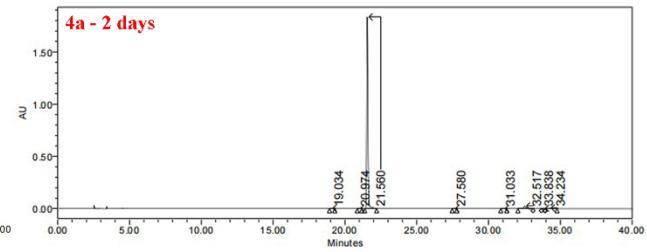

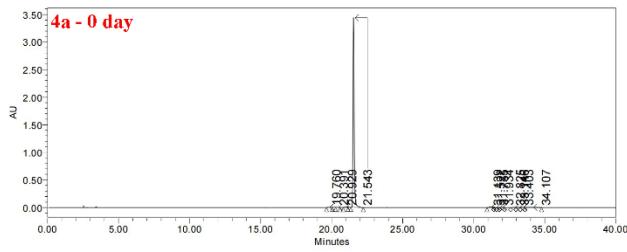

Time	Solution (A) %	Solution (B) %
0 to 10 min	90	10
10 to 20 min	60	40
20 to 28 min	30	70
28 to 30 min	5	95
30 to 40 min	90	10

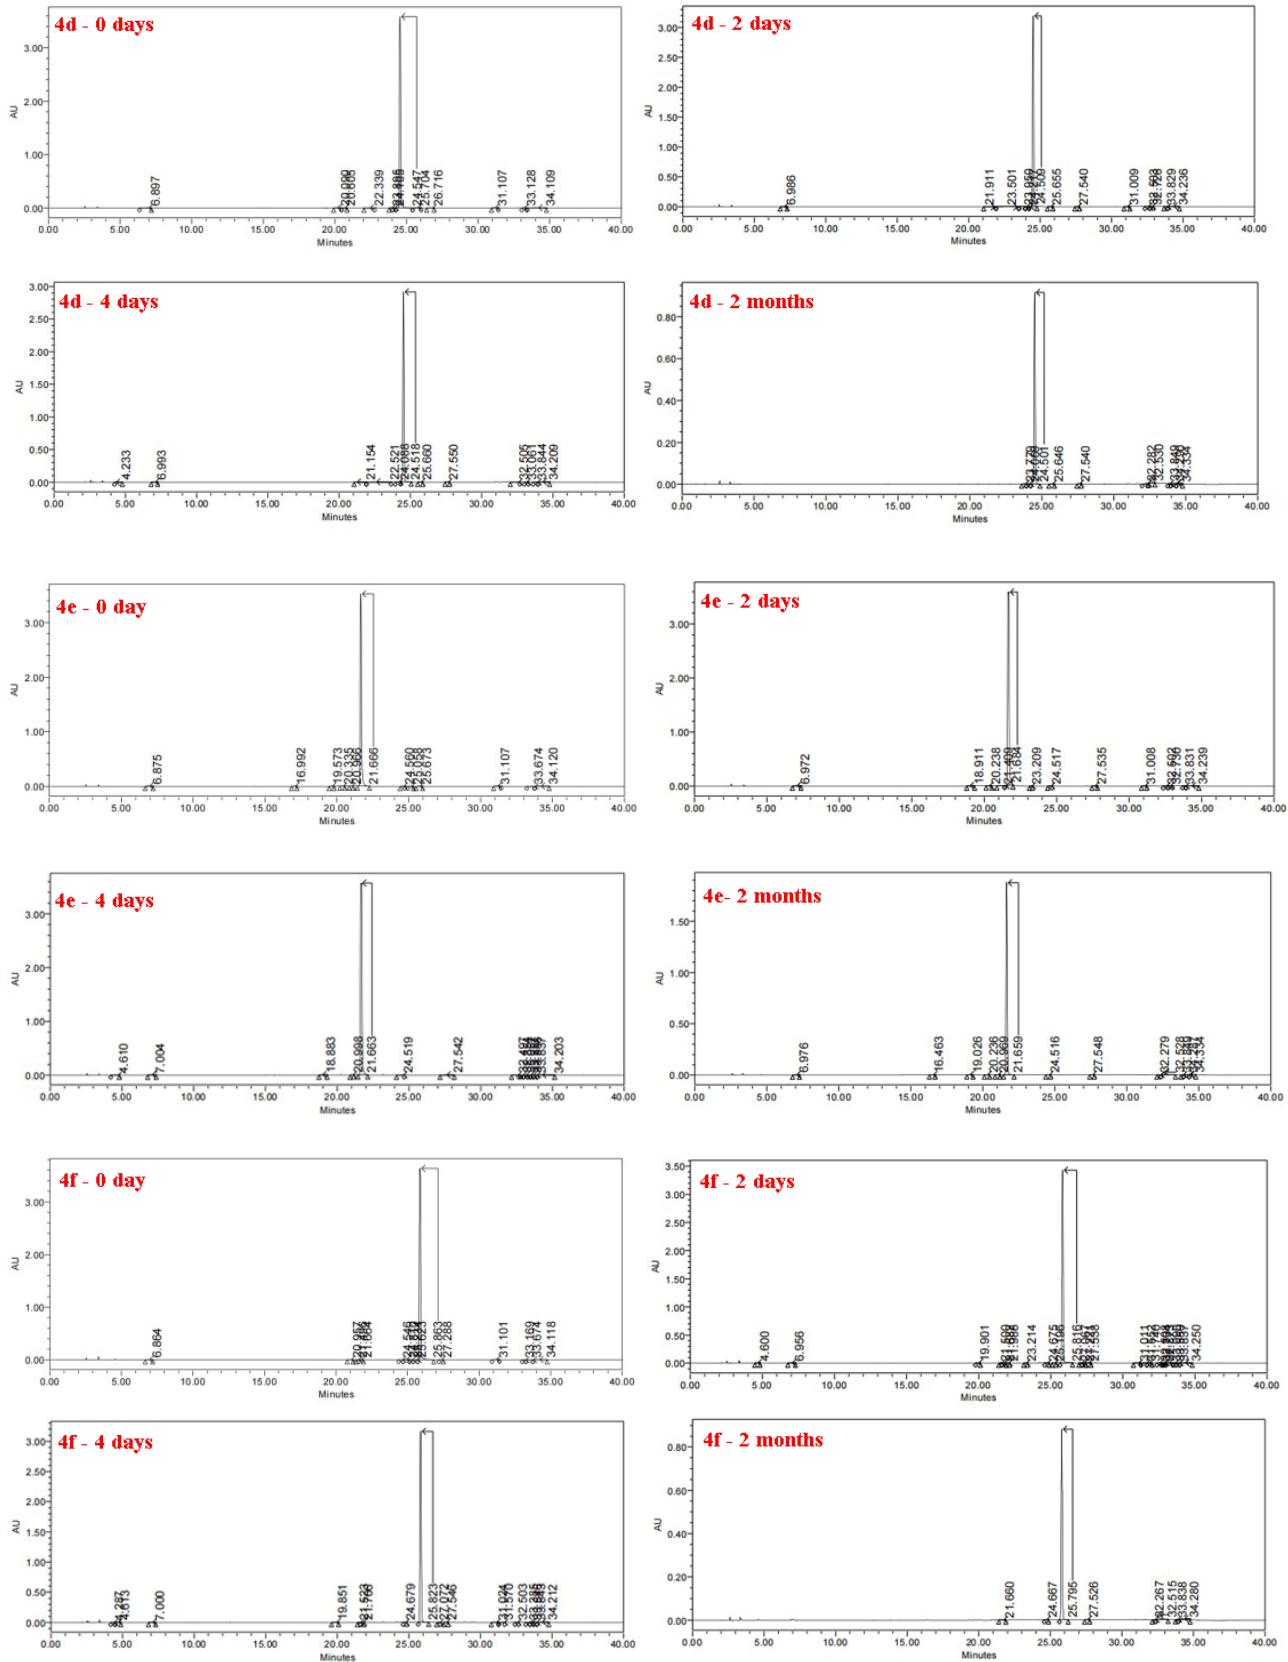

Table S2. The stability of the synthesized compounds in aqueous solution.

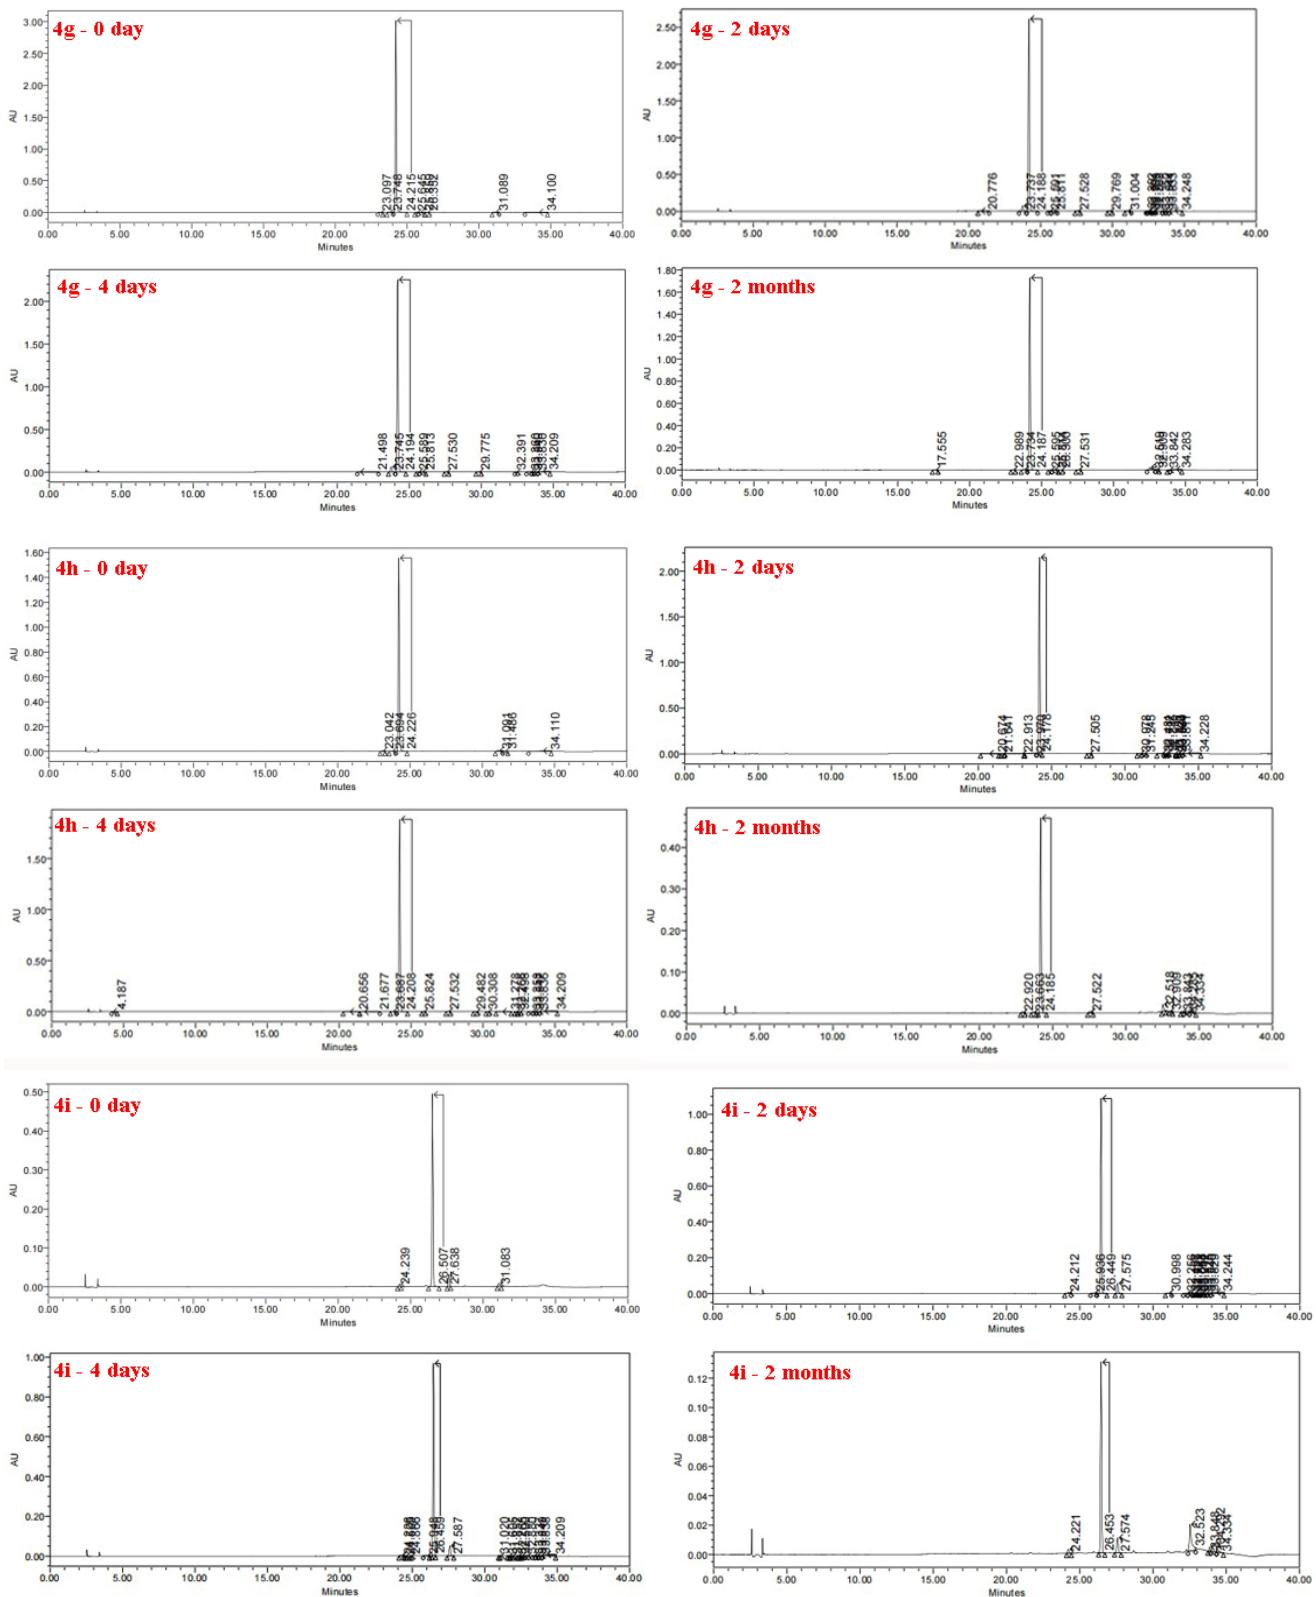

Each compound (2.0 mg) was dissolved in an appropriate volume of water to achieve an approximate concentration of 1-2 mg/mL. The solutions were then subjected to ultrasonic treatment, filtered, and analyzed. During stability testing, varying degrees of crystal precipitation were observed in all samples over time. To facilitate analysis, these samples were reconstituted with additional water or treated ultrasonically, filtered, and then HPLC analysis.

The UV spectra of all synthetic compounds in the mobile phase showed maximum absorption at approximately 275 nm, which was selected for detection. The integration method employed was based on the minimum area approach to accurately determine the retention time (min) and main peak area (%) of all synthesized compounds. The prepared samples were stored at room temperature, and their stability in aqueous solution was evaluated at 0, 2, 4 days, and 2 months using the aforementioned analytical method.

Compounds	0 day		2 day		4 days		2 months	
	RT	Area	RT	Area	RT	Area	RT	Area
4a	21.543	97.61	21.560	95.84	21.618	95.76	21.511	91.27
