Abstract: The Yunnan geothermal area has many neutral and alkaline thermal springs. Members of the genus *Thermus* have been found in thermal environments. In this study, we attempted to cultivate numerically abundant *Thermus* species using a variety of different strategies. A total of 223 strains of *Thermus*-like bacteria were isolated from seventeen hot spring samples of four geothermal regions (Baoshan, Dali, Lincang and Dehong). These strains were classified into two genera, *Thermus* and *Meiothermus*, based on 16S rDNA. The optimal isolation temperature of the *Thermus* genus was 63–70 °C. The highest *Thermus* diversity was found at 63 °C. *Thermus brockianus* was a universal culturable bacterium in the four geothermal regions. The principal component analysis (PCA) showed that *T. oshimai* preferred to inhabit the hot springs of the Baoshan (Bs) geothermal region, and *T. amyloliquefaciens* dominated the Dali (Dl) geothermal region, whereas *T. tengchongensis* accumulated in the Lincang (Lc) and Dehong (Dh) geothermal regions. The results suggested that *Thermus* species had habitat-preferable characteristics among the four geothermal regions. The findings may help identify the niche from which *Thermus* strains can likely be isolated.

Keywords: cultivation-dependent method; geothermal region; thermal spring; *Thermus* diversity

1. Introduction

Yunnan Province, one of China's best-known volcanic geothermal areas, is located in southwestern China. It is located at the collision boundary between the Indian and Eurasian plates and is an integral part of the Mediterranean-Himalayan geothermal belt. As a result of post-volcanism and an active geothermal system, there are many neutral and alkaline thermal springs in this area. These thermal springs are mainly located in Tengchong County in the Baoshan region, Eryuan County in the Dali region, Yun County in the Lincang region and Lianghe County in the Dehong region of Yunnan Province. Of these, Tengchong springs have been extensively studied by microbiologists using cultivation-independent approaches [1–9] and cultivation-dependent methods [10–18]. For the other geothermal systems, with the exception of a few surveys [19,20], many thermal springs in the Yunnan geothermal area have not yet been studied in detail.

Since Brock et al. [21] isolated and named the extreme thermophile *Thermus aquaticus* from Yellowstone National Park, many strains of *Thermus* have been isolated from neutral to alkaline thermal environments around the world [22]. However, only 18 (scientific) names are valid species because most isolates are phylogenetically closely related (<https://lpsn.dsmz.de/genus/thermus>, accessed on 10 September 2021). Out of 18 *Thermus* species, 16 species, including *T. brockianus*, *T. thermophiles*, *T. oshimai*, *T. caliditerrae*, *T. arciformis*, *T. islandicus*, *T. igniterrae*, *T. antranikianii*, *T. tengchongensis*, *T. amyloliquefaciens*, *T. caldilimi*, *T. aquaticus*, *T. caldifontis*, *T. filiformis*, *T. profundus* and *T. tenuipuniceus* have been found in

hot springs around the globe, among the other two species, *T. composti* was isolated from an oyster mushroom compost, and *T. scotoeductus* was isolated from a South African gold mine. The typical characteristics of the genus *Thermus* are Gram-stain-negative, aerobic and rod-shaped. Most species form yellow colonies and grow optimally at 60–70 °C. Several *Thermus* species have shown biotechnological potential, such as enzymes from *Thermus aquaticus* and *T. thermophilus*, which have exhibited higher activity and stability than synthetic or enzymes from mesophilic organisms [23,24]. Reduction of heavy metals from *T. scotoeductus*, which is essential for the removal of heavy metal pollution and the removing of organic contaminants in water [25,26].

Over 50 strains identified as *Thermus* have been isolated from hot springs in Tengchong [27–29]. However, most of these *Thermus* strains have remained unclassified, or some were identified as '*Thermus rehai*', but the name is not validly published. A few studies have reported the isolation and diversity of the genus *Thermus* from hot springs in Yunnan Province, southwestern China. To further understand the diversity and distribution of *Thermus* species in Yunnan province, southwestern China, we attempted to cultivate numerically abundant species using a variety of different strategies. Enrichment conditions (various temperatures and media) were designed to favor the recovery of species adapted to the temperatures and substrates. In the course of this work, we isolated and characterized *Thermus* strains, and our results reveal the diversity of *Thermus* isolates within one region or between regions whose distribution may be controlled by specialized adaptation to environmental features.

2. Materials and Methods

2.1. Sampling Area and Sample Collection

Seventeen hot springs and effluent channel samples were collected from ten hot springs and examined based on contrasting characteristics, such as pH, temperature and location in four geothermal regions (Lincang region (Lc), Baoshan region (Bs), Dali region (Dl) and Dehong region (Dh)) of western Yunnan Province, southwestern China. These hot springs have not been developed, and most of them are in farmers' homes. So, these hot springs have been named; here we give a number for a hot spring. The temperature and pH of the hot springs or effluent channels were recorded at the time of sampling (Table 1). Water, sediment and microbial mat samples were collected from each hot spring, and then the samples were aseptically transferred to sterilized 250 mL Erlenmeyer flasks, stored at room temperature and processed within a few hours before examination in the laboratory.

2.2. *Thermus* Strain Isolation and Culture Conditions

Three media were used to isolate *Thermus* strains from the hot spring samples: (1) Castenholz medium (DSMZ medium 86), (2) *Thermus* 162 medium (DSMZ medium 878) and (3) *Thermus* rubber medium (DSMZ medium 256). The above media were adjusted to different pH values (pH 7.0–8.5) according to the pH of the hot spring samples (Table 1). A series of dilution isolation methods was used: first, samples (water, sediment and microbial mats) from the same hot spring were mixed thoroughly for 1 h, and then the mixed samples (5 g) were blended with sterile water (45 mL) for 2 min, followed by five serial dilutions with sterilized water. Amounts of 200 µL of the 10⁻³, 10⁻⁴ and 10⁻⁵ dilutions of each sample were spread on the surface of the 3 solid media. All plates were incubated at different temperatures (50, 55, 63, 70, 75 °C) for 2 to 4 days (Table 1). Due to most strains of genes *Thermus* being yellow-pigmented, colonies that showed cultural characteristics of this genus were counted, as well as colonies of other bacteria. During this period, the plates were checked daily for the presence of *Thermus*-like strain colonies. *Thermus*-like strains were picked out and purified on Castenholz medium plates at 55 °C and were then transferred to Castenholz medium slants for storage at 4 °C.

2.3. DNA Extraction and PCR Amplifications

Complete genomic DNA was extracted as described by Cui et al. [30] with some modifications. Approximately 50 mg of biomass collected by scraping cells from the Castenholz

medium plates was incubated for 1 h at 37 °C in 480 µL TE extraction buffer (pH 8.0; 10 mM Tris-HCl, 1 mM EDTA) and 20 µL lysozyme (50 mg/mL; Biosharp, Guangzhou, China). Then, 50 µL SDS (20%, *w/v*; Tiandz, Beijing, China) and 5 µL protease K (20 µg/mL; BioFroxx, Guangzhou, China) were added for further incubation for 1 h at 55 °C. Subsequently, the lysate was extracted with a phenol-chloroform-isoamyl alcohol solution (25:24:1; Tiandz), and DNA was recovered by sodium acetate and isopropanol precipitation. The pellet was washed with 70% (*v/v*) ethanol, dried under vacuum and resuspended in 50 µL TE buffer (pH 8.0; 10 mM Tris-HCl, 1 mM EDTA). Genomic DNA was stored at −20 °C.

Table 1. The sample characteristics and isolation conditions of the four geothermal regions of southwestern Yunnan Province. /, Not data available.

Geothermal Region	Hot Spring	Sample	Sample Temperature (°C)	Sample pH	Isolation Temperature (°C)	Isolation pH
Lincang (Lc)	4	4-1	75.3	6.92	50, 55, 63, 70, 75	7.0
		5-1	/	/		
	5	5-2	91.5	9.20		8.5
		5-3	/	/		
Baoshan (Bs)	6	6-1	93.0	8.17	8.0	
		8A	8-1	79.9		6.34
	8B	8-2	/	/	50, 55	7.0
		8-3	54.8	6.90	7.0	
8C	8-4	/	/	50, 55, 63, 70		7.0
	8-5	72.7	6.62	7.0		
Dali (Dl)	16	16-1	56.9	7.21	50, 55, 63, 70	7.0
		17-1	71.1	6.48		
	17A	17-2	74.8	6.63		7.0
		17-3	/	/		
18	18-1	75.0	6.64	50, 55, 63, 70, 75	7.0

13-2		/	/			

The 16S rRNA genes were amplified as described by Cui et al. [30] with a Perkin-Elmer 2400 thermal cycler (Perkin-Elmer Cetus Co., Norwalk, CT, USA); 27F (5'-AGAGTTTGA TCMTGGCTCAG-3') and 1492R (5'-TACGGYTACCTTGTTACGACTT-3') primers [31] were used. The amplification program consisted of pre-denaturation at 95 °C, 4 min; 30 cycles at 95 °C, 30 sec; 56 °C, 30 sec and 72 °C, 1 min and 30 sec; and a final extension at 72 °C for 5 min. The final products were analyzed by electrophoresis on 1% agarose, and the molecular weights of amplified DNA were estimated by comparison with the *E. coli* λT14 (TaKaRa, Kusatsu, Japan) DNA ladder.

2.4. Sequence Classification and Phylogenetic Analysis

The sequencing of PCR products was performed using single-pass Sanger sequencing with primer 27F on an Applied Biosystems DNA sequencer (model 3730 XL), and the length of all sequences exceeded 700 bp. The 16S rRNA gene sequences were compared within the NCBI database (<http://www.ncbi.nlm.nih.gov/Blast> (accessed on 17 April 2020) using the Basic Local Alignment Search Tool (BLAST) to determine the relative phylogenetic positions. Phylogenetic analysis was conducted using MEGA 6.0 [32] by first generating a complete alignment of 16S rRNA gene sequences of the isolates and type strains of all validly published species within the gene *Thermus*. Dendrograms were generated from K_{nuc} values [33] using the neighbor-joining (NJ) method of Saitou and Nei [34], and bootstrapping was carried out using 1000 replications. The 16S rRNA sequences from the representative strains in different species were deposited in GenBank under accession numbers MH827613 to MH827835.

2.5. OTU Assignment and Community Analysis

All good-quality sequences were aligned with CLUSTALX 1.83 [35] and were assigned to operational taxonomic units (OTUs) based on a cutoff value of 0.03 using DOTUR software [36]. The OTU-based similarity or dissimilarity between the culturable communities in 4 geothermal regions was calculated by “SIMPER” analysis using PAST software [37,38]. The contributions of the OTUs to the similarity or dissimilarity were calculated based on the relative abundances of OTUs between the groups. Clustering trees and principal component analysis (PCA) plots were created between the samples based on the average Bray–Curtis similarity of OTU compositions in the different geothermal regions.

3. Results

3.1. Screening of the Culturable *Thermus*-Like Strains from the Four Geothermal Regions

A total of 17 samples from 10 hot springs, including hot spring water, sediment and microbial mats, were collected from four geothermal regions in August 2011. These hot springs exhibited heterogeneity with regard to temperature, pH and conductivity. The temperature at the sampling sites varied from 54 to 93 °C, the pH from 6.3 to 9.2 and the conductivity from 563 to 2756 $\mu\text{S}/\text{cm}$ (Lc: 75–93 °C, pH 6.9–9.2, 659–2756 $\mu\text{S}/\text{cm}$; Bs: 54–80 °C, pH 6.3–6.9, 1106–1164 $\mu\text{S}/\text{cm}$; DI: 71–75 °C, pH 6.4–7.2, 1459–1534 $\mu\text{S}/\text{cm}$; Dh: 79 °C, pH 7.92, 578 $\mu\text{S}/\text{cm}$) (Table 1). After the screening, with the exception of 23 *Meiothermus* strains, a total of 200 strains of *Thermus* were obtained from the 17 hot spring samples using three different media, and 30 to 80 strains were obtained from each geothermal region (Table 2). An OTU-based analysis of the 16S rRNA gene was conducted. At a 3% cutoff, which is generally considered the label for species, a total of 11 OTUs were obtained (Supplementary Table S1). The classification of the OTUs against the NCBI and RDP 16S rRNA reference databases is shown in Table 2.

3.2. Species of Culturable *Thermus*-Like Bacteria in the Lincang Geothermal Region

Among the 11 OTUs, eight OTUs were isolated from the Lc geothermal region, seven OTUs were isolated from the Bs geothermal region, five OTUs were isolated from the Dh geothermal region and four OTUs were isolated from the DI geothermal region (Figure 1 and Supplementary Table S1). Consequently, the community structure was studied specifically in the four geothermal regions.

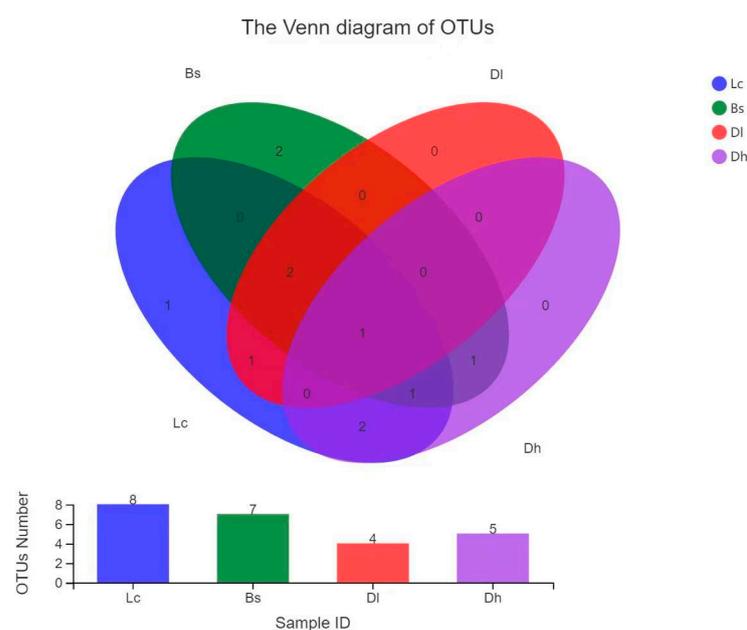

Figure 1. Venn diagram of OTUs at a cutoff of 0.03 for the *Thermus*-like bacteria in four geothermal regions. The numbers in the overlapping parts represent the shared OTUs among different regions.

Table 2. Distribution characteristics of *Thermus*-like strains from different hot springs of four geothermal regions of southwestern Yunnan Province.

OTU	Taxon	Hot Spring/Hot Spring Temperature (°C)									Isolaton Temperature (°C)					
		4/75.3	5/91.5	6/93.0	8A/79.9	8B/54.4	8C/72.7	16/56.9	17A/75.3	18/71.1	13/79.0	50	55	63	70	75

OTU11	<i>Meio. ruber</i>			1	20			1				7	7	8		
	Total number	13	32	35	38	7	23	1	15	29	30	7	33	68	72	43

In the Lc geothermal region samples, eight OTUs composed of a group of 80 strains of *Thermus*-like bacteria were isolated and screened using three *Thermus* media and five temperature conditions. After sequence assignment against the NCBI and RDP databases, they were clustered into two genera of the family *Thermaceae*, i.e., *Thermus* and *Meiothermus* (Figure 2 and Table 2). In the genus *Thermus*, *Thermus tengchongensis* was the most abundant culturable species, which was composed of 30 strains, followed by 16 strains of unclassified *Thermus* sp., 13 strains of *T. oshimai*, 11 strains of *T. brockianus*, 5 strains of *T. igniterrae*, 3 strains of *T. amyloliquefaciens* and 1 strain of *T. arciformis*. In addition, one strain was isolated and classified into the genus *Meiothermus* in the hot spring samples of this geothermal region.

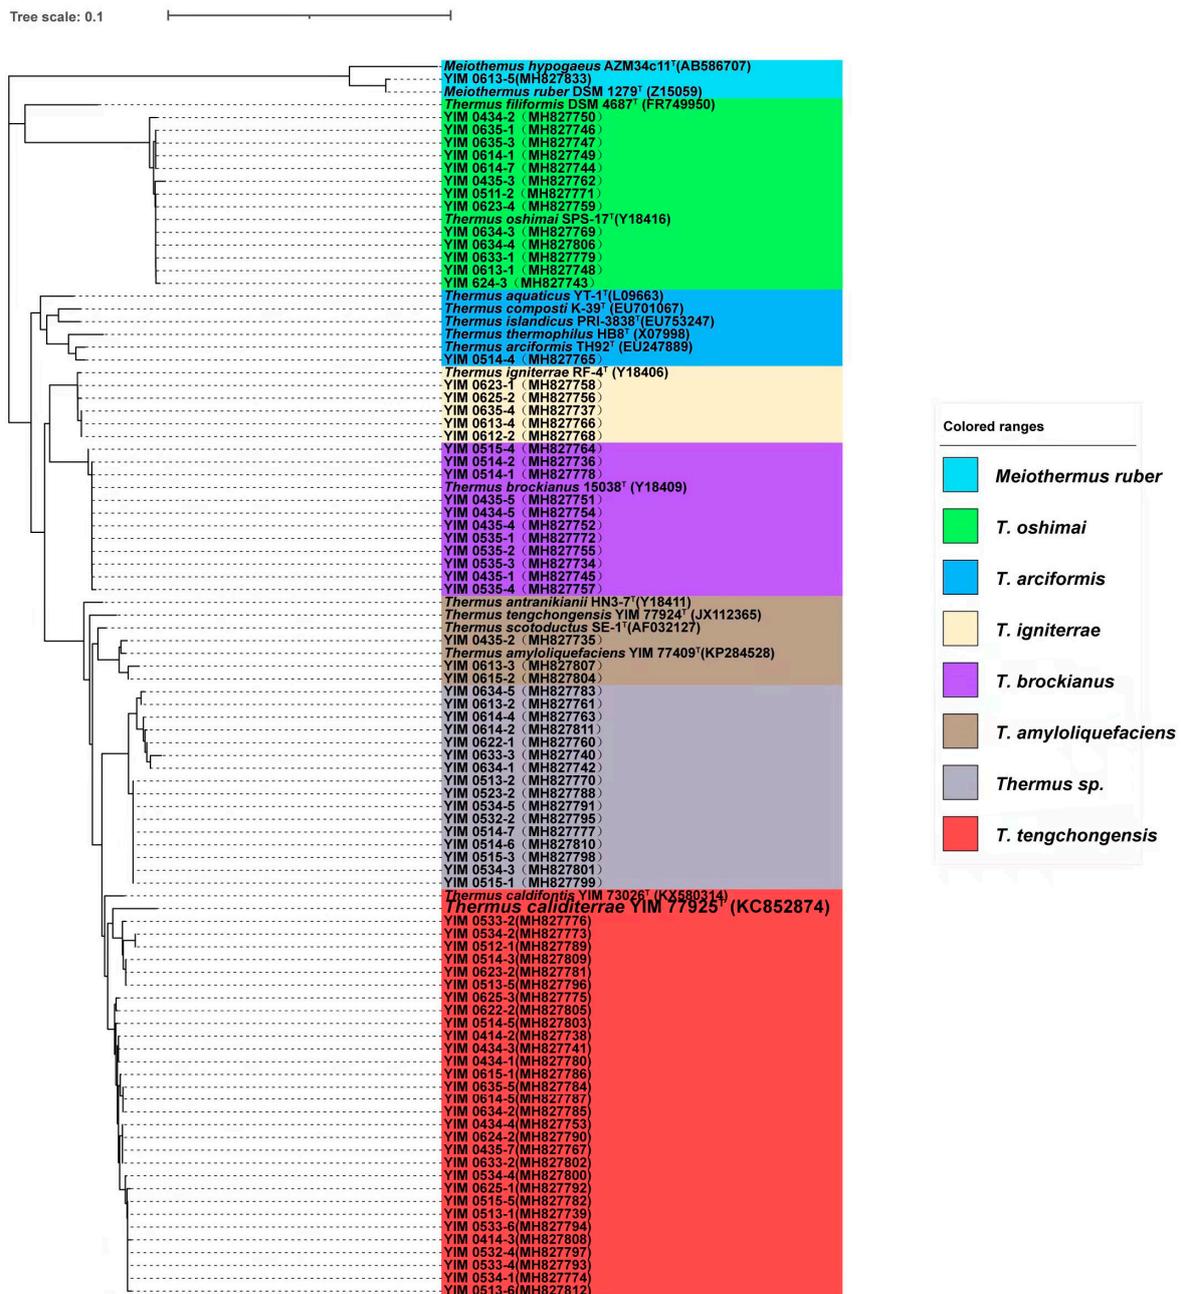

Figure 2. The phylogenetic tree for the culturable *Thermus* strains in the Lincang geothermal region. Numbers at nodes indicate bootstrap values (>50%) based on a neighbor-joining analysis of 1000 resampled datasets. The vertical scale bar in the middle represents 0.1 substitutions per nucleotide position.

3.3. Species of Culturable *Thermus*-Like Bacteria in the Baoshan Geothermal Region

In the Bs geothermal region samples, seven OTUs composed of a group of 68 strains of *Thermus*-like bacteria were isolated and screened using three *Thermus* media and five temperature conditions. After sequence assignment against the NCBI and RDP databases, they were clustered into two genera of the family *Thermaceae*, i.e., *Thermus* and *Meiothermus* (Figure 3 and Table 2). In the genus *Thermus*, *Thermus oshimai* was the most abundant culturable species in this geothermal region, which was composed of 31 strains, followed by 9 strains of *T. brockianus*, 3 strains of *T. arciformis*, 3 strains of *T. caliditerrae* and 1 strain of an unclassified *Thermus* sp. Another 21 strains were affiliated with 2 species of the genus *Meiothermus*, 20 strains were affiliated with *Meiothermus ruber*, and the last 1 belonged to *Meiothermus hypogaeus*.

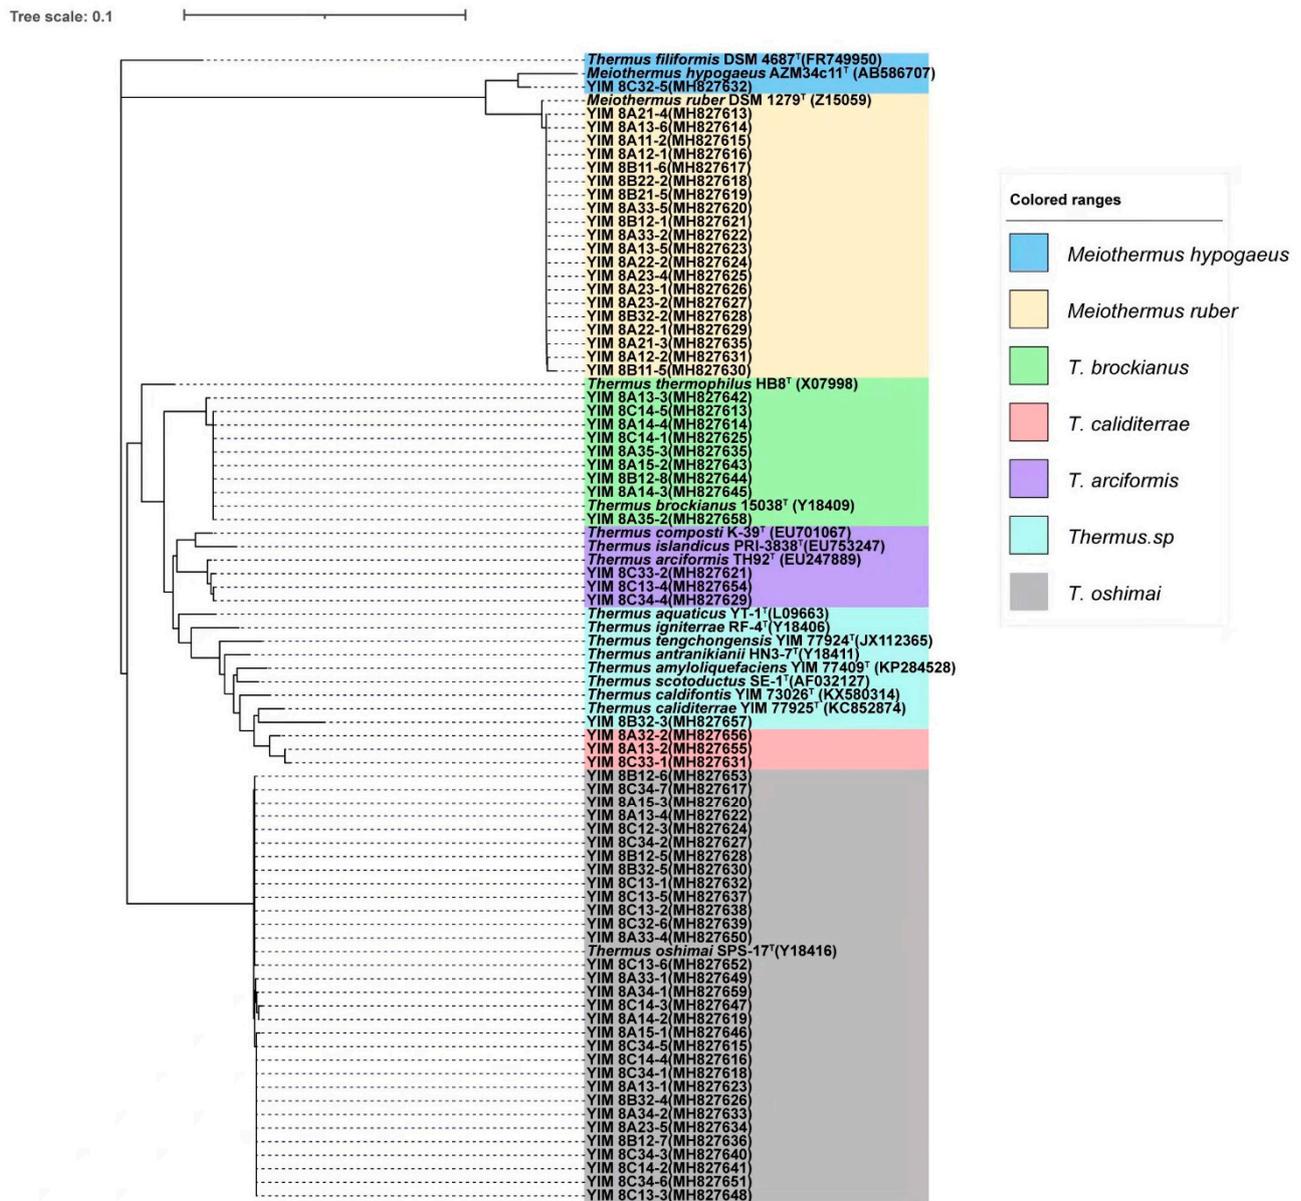

Figure 3. The phylogenetic tree for the culturable *Thermus* strains in the Baoshan geothermal region. Numbers at nodes indicate bootstrap values (>50%) based on a neighbor-joining analysis of 1000 resampled datasets. The vertical scale bar in the middle represents 0.1 substitutions per nucleotide position.

3.4. Species of Culturable *Thermus*-Like Bacteria in the Dali Geothermal Region

From the D1 geothermal region, four OTUs, composed of a group of 45 strains of *Thermus*-like bacteria, were isolated from hot spring water and sediment collected in this geothermal region and were screened using three *Thermus* media and four temperature conditions (Figure 4 and Table 2). After the sequence assignment against the NCBI and RDP databases, two genera of the family *Thermaceae* were assigned, i.e., *Thermus* and *Meiothermus* (Figure 4). *Thermus amyloliquefaciens* was the predominant culturable *Thermus* species, containing 30 strains. In addition, 13 strains of *T. brockianus* and 1 strain of *T. oshimai* were also detected. Another strain belonged to *Meiothermus ruber*.

Figure 4. The phylogenetic tree for the culturable *Thermus* strains in the Dali geothermal region. Numbers at nodes indicate bootstrap values (>50%) based on a neighbor-joining analysis of 1000 resampled datasets. The vertical scale bar in the middle represents 0.1 substitutions per nucleotide position.

3.5. Species of Culturable *Thermus*-Like Bacteria in the Dehong Geothermal Region

In this study, five OTUs, composed of a group of 30 strains of *Thermus*-like bacteria, were detected from hot spring water and sediment collected in this geothermal region and screened using three *Thermus* media and five temperature conditions (Figure 5 and Table 2). After sequence assignment against the NCBI and RDP databases, 30 strains were assigned to the genus *Thermus* (Figure 5). *Thermus tengchongensis* was the predominant culturable species, containing 19 strains. Eight strains of *T. igniterrae*, one strain of *T. brockianus*, one strain of *T. arciformis* and one strain of *T. calditerrae* were also detected.

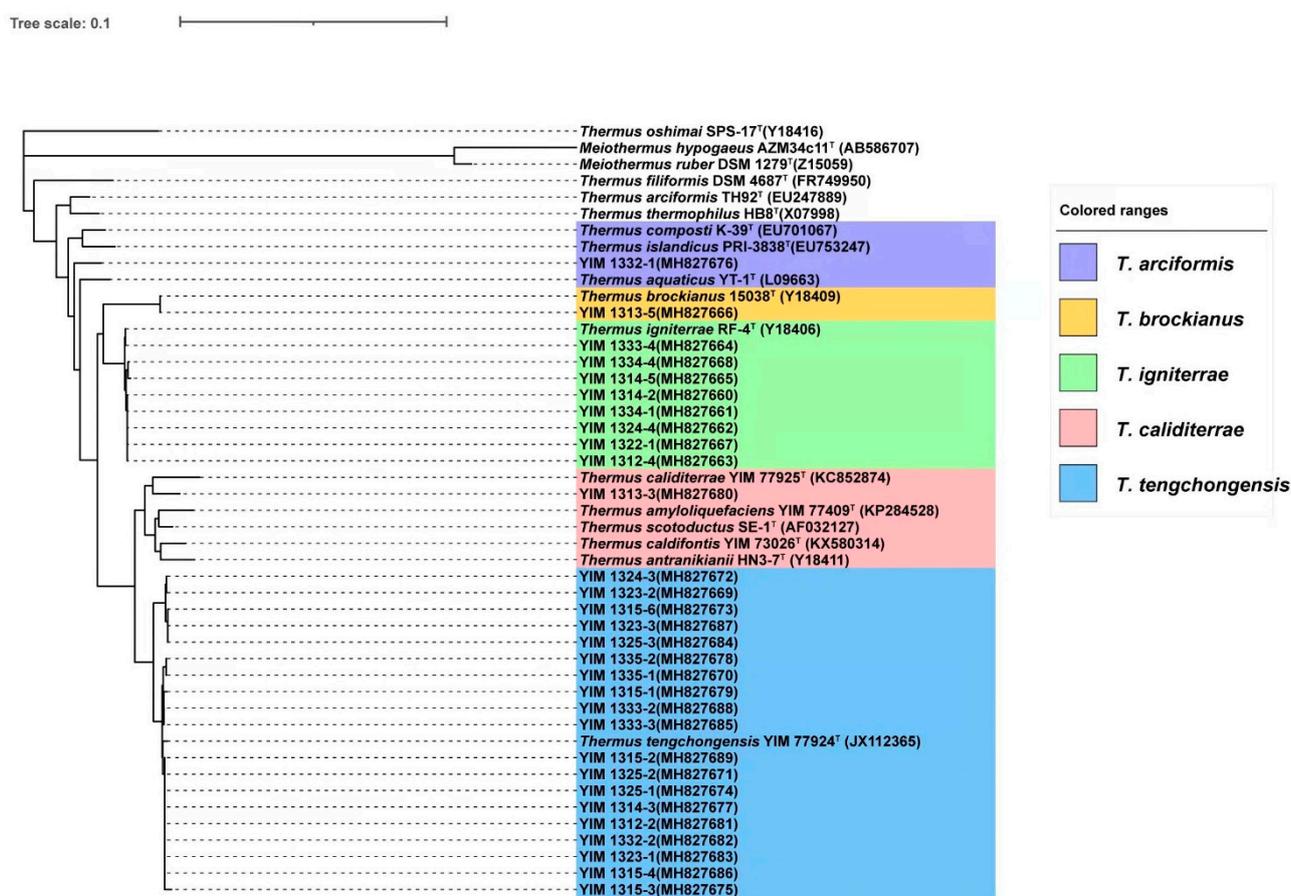

Figure 5. The phylogenetic tree for the culturable *Thermus* strains in the Dehong geothermal region. Numbers at nodes indicate bootstrap values (>50%) based on a neighbor-joining analysis of 1000 resampled datasets. The vertical scale bar in the middle represents 0.1 substitutions per nucleotide position.

3.6. Distribution of Culturable *Thermus*-Like Bacteria in the Four Geothermal Regions

To compare the habitat preference of the culturable *Thermus*-like bacteria, the beta-diversity of these bacteria was studied between the four geothermal regions in southwestern Yunnan Province. Samples from the hot springs in the Lc and Bs, Dl, and Dh geothermal regions shared the highest number of OTUs (four OTUs), in comparison with the Bs and Dl hot springs (three OTUs), Bs and Dh hot springs (three OTUs) and Dl and Dh hot springs (one OTU) (Figure 1). Only one OTU was shared among all four regional hot spring samples, which was OTU 1 (*T. brockianus*). Figure 6 shows that *Thermus*-like bacteria in the four regional samples could be clustered into five groups based on OTU composition. The culturable *Thermus*-like bacteria had low similarity in the four geothermal regions. *Thermus* species of the hot springs in the Lc geothermal region had a relatively closer relationship (24% Bray–Curtis similarity) with the *Thermus*-like bacteria of the hot springs in the Bs geothermal region. Based on SIMPER analysis in PAST, OTU 6 (*T. tengchongensis*) contributed most to the Bray–Curtis dissimilarity (22.8% contribution), followed by *T. oshimai* (19.9% contribution), *T. amyloliquefaciens* (16.3% contribution) and *T. brockianus* (11.8% contribution), which together contributed 70.8% of the Bray–Curtis dissimilarity. This implied that these species might have habitat preferences in the hot springs of the four geothermal regions.

The PCA plot indicated that OTU 1 (*T. oshimai*) and OTU 11 (*Meio. ruber*) preferred to inhabit the hot springs of the Bs geothermal region rather than the hot springs of the Lc, Dh and Dl geothermal regions (Figure 7). For example, OTU 1 (*T. oshimai*) accounted for 16.3% and 2.2% of the culturable *Thermus*-like bacteria in the Lc and Dl hot springs, respectively, but no strains of OTU 1 were isolated from the Dh hot springs (Table 2). OTU 3 (*T. igniterrae*) and OTU 6 (*T. tengchongensis*) contributed most to the dissimilarity between

the Lc and Dh geothermal regions and the two other geothermal regions. Specifically, OTU 8 (unclassified *Thermus*) was only isolated from hot springs in the Lc geothermal region and had a relative abundance of 20% in this region (Table 2). In the D1 geothermal region, OTU 2 (*T. brockianus*) and OTU 4 (*T. amyloliquefaciens*) contributed most to the dissimilarity between this geothermal region and the three other geothermal regions (Figure 7). In particular, OTU 4 (*T. amyloliquefaciens*) was the most abundant culturable *Thermus* strain, accounting for 66.7% of *Thermus* strains in this geothermal region. However, a lower abundance (3.8%) was detected in the Lc geothermal region (Table 2), and no strains were obtained from the two other geothermal regions. OTU 2, which was the only OTU among all four regional hot spring samples, was the second most abundant culturable *Thermus* strains and accounted for 28.9% of the relative abundance. In addition, OTU 9 (unclassified *Thermus*) and OTU 11 (*Meiothermus hypogaeus*) were only isolated from the BS geothermal region, and both had a relative abundance of 2.9%. The culturable *Thermus* strains presented 65% dissimilarity among the hot springs of the four geothermal regions.

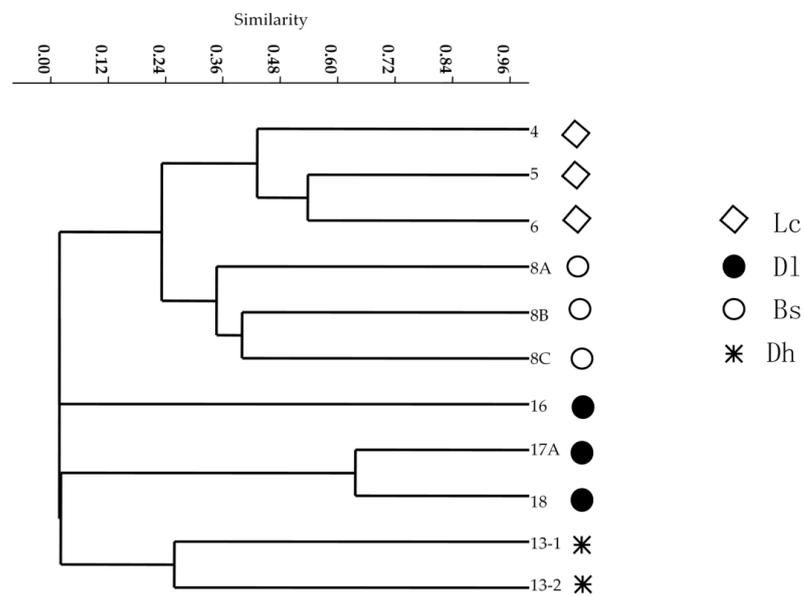

Figure 6. Cluster analyses of the culturable *Thermus*-like bacterial community structure in the hot springs of four geothermal regions based on Bray–Curtis similarity.

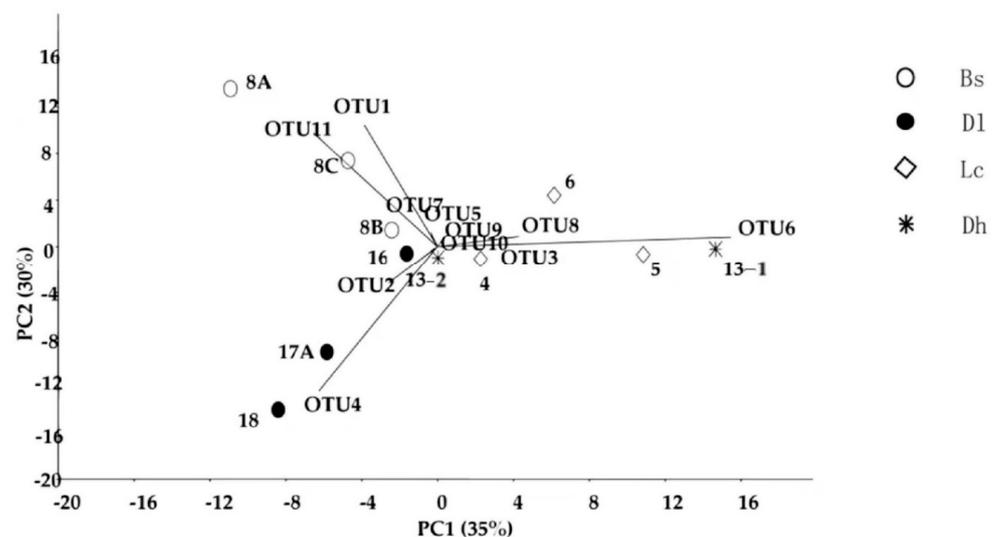

Figure 7. The PCA biplot and dominant OTUs corresponding to the dissimilarity of *Thermus*-like species in the hot springs among the four geothermal regions.

4. Discussion

In this study, the highest *Thermus* diversity was found at 63 °C, and under this isolation temperature, nine OTUs were detected (Table 2). This conclusion was supported by previous studies, in which *Meiothermus* had a lower optimal temperature growth range (50–60 °C) than *Thermus* strains (65–75 °C) [22,39,40]. *T. brockianus* was the most abundant species in the four geothermal regions, indicating that this may be a universal culturable *Thermus* species in southwestern Yunnan Province. A total of 13 strains were found in 2 D1 hot spring samples under 4 isolation temperatures (55, 63, 70 and 75 °C), 11 strains were found in 2 Lc hot spring samples with isolation temperatures of 70 and 75 °C, 9 strains were found in 3 Bs hot springs with isolation temperatures of 63, 70 and 75 °C, and 1 strain was found in a Dh hot spring with an isolation temperature of 75 °C. The optimum isolation temperature of *T. brockianus* was 70–75 °C (Table 2). The conclusion here was supported by previous studies in which *T. brockianus* was reported to have a broad global distribution across hot springs in Iceland [41,42], Yellowstone National Park in the US [23,43] and the Rehai region of Tengchong County in Yunnan Province, China [28]. *T. oshimai* is another *Thermus* species that was isolated from hot springs in Portugal, Iceland and Azores [44], the Great Basin in the US [45] and the Rehai region of Tengchong County in China [27]. In this study, 45 strains, which were isolated from three geothermal regions at an optimum isolation temperature of 63–70 °C, clustered with *T. oshimai* with 98.87–100% sequence similarities. These strains dominated in Bs hot springs (31 out of 45) and Lc hot springs (13 out of 45) with one strain from the D1 hot springs. *Thermus amyloliquefaciens* was a recently named *Thermus* species isolated from the Niujie hot spring of the D1 geothermal region, Yunnan Province, China [19]. In this study, 33 strains from two geothermal regions had 98.03–99.65% sequence similarities to *T. amyloliquefaciens* YIM 77409^T. *Thermus amyloliquefaciens* was also predominantly isolated from hot springs in the D1 geothermal region, with an optimum isolation temperature of 63–70 °C. Another three isolates were detected in Lc hot springs. Another abundant *Thermus* species, *Thermus thengchongensis*, was found in heated soil samples collected in Rehai National Park, Tengchong [17]. By contrast, *T. thengchongensis* was not detected in Tengchong hot springs in the Bs geothermal region. In this study, 30 strains of *T. thengchongensis* were isolated from the Lc geothermal region, and 20 strains were isolated from the Dh geothermal region with an optimum isolation temperature of 70–75 °C (Table 2).

In addition to the abundant *Thermus* species, strains of other *Thermus* were also detected in this study, such as *T. igniterrae*, *T. arciformis* and *T. caliditerrae*. Thirteen strains (eight from Dh hot springs and five from Lc hot springs) were similar to *T. igniterrae* (99.65–99.89% sequence similarities), which were primarily isolated from hot springs in Iceland [46]. Therefore, this study is the first to report that *T. igniterrae* was isolated from the hot spring samples of Yunnan Province in China with an isolation temperature of 55–75 °C (Table 2). Five strains (three from Bs hot springs, one from Dh hot springs and one from Lc hot springs) could be classified as *T. arciformis* with 98.14–99.44% sequence similarities; this species was isolated from the Tibet hot springs in China [20]. Four strains (three from Bs hot springs and one from Dh hot springs) could be classified as *T. caliditerrae*, with 98.14–99.44% sequence similarities. This species was recently isolated from the Tengchong geothermal region of Yunnan province, China [18]. Some other *Thermus* species were first reported in this study, including seventeen isolates that could not be assigned to any described *Thermus* species (similarity < 97%). These strains formed two clusters in the phylogenetic tree, representing two potential novel species (*Thermus* sp. 1 and *Thermus* sp. 2), and strains from the same geothermal region clustered together. The optimum isolation temperature of those strains was 63–70 °C. Sixteen strains from Lc hot springs were related to *T. scotoductus* (96.1–97.0% sequence similarities). *Thermus scotoductus* was found to have a broad global distribution, being detected from hot springs in Iceland [47], South Africa [48], New Mexico [41] and Portugal [49]. One isolate from Bs hot springs formed a single branch, and it was related to *T. caliditerrae* (95.24% sequence similarity); this isolate may represent a novel species.

5. Conclusions

To isolate the *Thermus*-like strains, it is necessary to design isolation procedures that can be adapted to isolate this community. In this study, three media and four or five temperatures were selected to isolate culturable *Thermus*-like strains (Table 1). In total, 223 yellow/red-pigmented colonies of *Thermus*-like bacteria were obtained from 17 hot spring samples of the four geothermal regions. At 50 °C, only seven *Thermus*-like strains were isolated, and all seven strains were affiliated with the genus *Meiothermus*. Another 16 strains belonging to the genus *Meiothermus* were isolated at 55 and 63 °C. Above 63 °C, no *Meiothermus* strain was detected (Table 1). In addition, at 55, 63 and 75 °C, 26, 59 and 43 *Thermus* strains were isolated, respectively. The optimum isolation temperature appeared to be 70 °C, and at this isolation temperature, 72 *Thermus* strains were isolated from the four geothermal regions. The highest *Thermus* diversity was found at 63 °C, and under this isolation temperature, nine OTUs were detected (Table 2).

The uneven distribution of richness shown by the Venn diagram (Figure 1) indicated that the structure of *Thermus*-like bacteria might be different among the four geothermal regions. The results of the cluster analysis showed that the samples from the same geothermal region were clustered into the same group in addition to the 16 hot spring samples of the D1 geothermal region. Culturable *Thermus*-like bacteria in the Dh and Lc geothermal regions had a closer relationship (nearly 24% Bray–Curtis similarity) relative to the culturable *Thermus*-like bacteria in the two other geothermal regions (Figure 6), implying that the culturable *Thermus*-like bacteria had more similar community compositions in the Dh and Lc geothermal regions in comparison with the two other geothermal regions. This result confirmed that the culturable *Thermus*-like bacteria had a niche preference among the four geothermal regions.

A total of 223 strains of *Thermus*-like bacteria isolated from the 4 geothermal regions were classified into 2 genera (*Meiothermus* and *Thermus*) and 11 species based on the colony color and 16S rRNA nucleotide sequence analyses. In this study, most isolates found in three geothermal regions belonged to *T. oshimai*. Only one species of *Thermus*, *T. brockianus*, was the dominant and universal culturable bacteria in all four geothermal regions. This species had different distribution characteristics among the four geothermal regions. In addition, two other species of *Thermus*, i.e., *T. amyloliquefaciens* and *T. tengchongensis*, were dominant culturable bacteria in these geothermal regions.

Supplementary Materials: The following are available online at <https://www.mdpi.com/article/10.3390/d13090455/s1>, Table S1: The *Thermus*-like bacteria in each OTU from four geothermal regions at cutoff 0.03.

Author Contributions: Writing—review and editing, Y.W.; Funding acquisition, X.C.; Methodology and strain isolation, Y.W. and L.H.; Data analysis, L.H. and C.X.; Data curation, C.L. and W.X. All authors have read and agreed to the published version of the manuscript.

Funding: This research was funded by National Natural Science Foundation of China (NSFC), grant number 31660001, 31660089, 31660042 and 31960220, and the Major Science and Technology Projects of Yunnan Province (digitalization, development and application of biotic resource), grant number 202002AA100007.

Institutional Review Board Statement: Not applicable.

Data Availability Statement: Not applicable.

Acknowledgments: We thank Qin He of Yunnan University for the helping of sample collection. We thank Ruihua You and Yan Liu of Yunnan University for comments on the manuscript.

Conflicts of Interest: The authors declare that they have no conflict of interest.
