Abstract: In a layer house, the CO₂ (carbon dioxide) concentration above the upper limit can cause the oxygen concentration to be below the lower limit suitable for poultry. This leads to chronic $CO₂$ poisoning in layers, which manifests as listlessness, reduced appetite, weak constitution, decreased production performance, and weakened resistance to disease. Regulating ventilation may ensure a suitable $CO₂$ concentration in layer houses. Predicting the changes in $CO₂$ concentration and regulating the CO² concentration in advance are key to ensuring healthy large-scale breeding of layers. In recent years, machine learning and deep learning methods have been increasingly applied to this field. A CO₂ prediction model for layer house is proposed based on a GRU (gated recurrent unit) and LSTM (long short-term memory). The temperature, humidity, and $CO₂$ were determined as inputs to the model by the correlation coefficient. The datasets of the experimental layer house were continuously measured during June–July 2023, using a self-developed environmental monitor, and the monitored data were used as samples for model inputs. There were 22,000 time series data in the datasets. In this study, multivariate time series data were standardized via data pre-processing to improve model training. GRU and LSTM models were constructed. The models were trained using a training set. Then, these trained models were used to provide predictions on a test set. The prediction errors were calculated using the true values of the test set and the predicted values provided by the models. To test the performance of the model and accuracy of the predictions, predictions were made for different numbers of datasets. The results demonstrated that the combined prediction model had good generalization, stability, and convergence with high prediction accuracy. Due to the structure of the model, the stability of the LSTM model was higher than that of the GRU model, and its prediction accuracy and speed were lower than those of the GRU model. When the datasets of the GRU model were 15,000 to 17,000, The MAE of the GRU was 70.8077 to 126.7029 ppm, and the prediction time of the GRU is 16 to 24 ms. When the LSTM model's datasets were 15,000–20,000, the MAE of LSTM was 78.8596 to 136.0896 ppm, and the prediction time of the GRU was 17 to 26 ms.

Keywords: layer house; CO₂ concentration; prediction; GRU; LSTM

1. Introduction

A closed layer house with stacked cages is a relatively closed environment. Thus, the environmental factors in the house, such as temperature, relative humidity, and harmful gases and dust concentrations, can substantially impact the growth, development, reproduction, production, and health of the poultry [\[1\]](#page-19-0). The harmful gases produced in a layer house not only pollute the environment but also affect the physical health of layers or

suppress their production potential, resulting in economic loss in the farming industry. These harmful gases mainly include $NH₃$ (ammonia), H₂S (hydrogen sulfide), and $CO₂$, which can be produced at harmful concentrations. Some of these harmful gases do not have a distinct odor and do not pose any serious hazards for short exposures and when at low concentrations. However, some gases damage health at high concentrations and result in acute symptoms, but this is less likely to occur under poultry production conditions. Long-term exposure to low concentrations of harmful gases causes progressive harm to both human staff and poultry health and reduces poultry productivity, causing the health status of the poultry to be poor, resulting in reduced immunity and reduced production performance. The symptoms of this condition can be easily confused with those of malnutrition or invasion by pathogenic microorganisms. Consequently, determining whether the poultry condition is due to the effects of long-term exposure to low concentrations of harmful gases can be difficult. Therefore, in modern farming and production, the air quality problem in livestock housing must be addressed [\[2\]](#page-19-1). In [\[3\]](#page-19-2), it is reported that $CO₂$ emission linearly increases with increasing layer age in days during broiler farming and production. Higher concentrations of NH_3 and CO_2 in animal barns can negatively affect production and health of animals and workers. Additionally, indoor and ambient environmental conditions such as temperature and relative humidity were measured simultaneously with pollutant gas concentrations [\[4\]](#page-19-3).

Pollutants emitted from poultry housing facilities are a concern from human health, bird welfare, and environmental perspectives. Development of emission factors for these aerial pollutants is difficult due to variable climatic conditions, the number and type of poultry, and the wide range of management practices used [\[5\]](#page-19-4).

In recent years, machine learning and deep learning methods have been increasingly applied to this field.

At present, prediction models for time series include SVM (support vector machine), ARIMA (autoregressive integrated moving average), and RF (random forest). The computational complexity of the SVM algorithm is relatively high, especially for large-scale and high-dimensional datasets, which require a large amount of computation time and space. In addition, the training process of the SVM algorithm requires multiple iterations, which also increases the computational complexity. The RF algorithm is more complex, computationally expensive, and requires more time to train than other algorithms [\[6\]](#page-19-5). The ARIMA model requires complete time series data with no missing values. In practical applications, there are often missing and incomplete data, which affects the effectiveness of the model [\[7](#page-20-0)[,8\]](#page-20-1).

The prediction method based on recurrent neural networks has advantages in terms of prediction accuracy and speed. In [\[9\]](#page-20-2), a novel PIHNN (physics-informed hybrid neural network) model based on the LSTM neural network is proposed. In [\[10\]](#page-20-3), Chinese stock returns were modeled and predicted using LSTM. The historical data of the Chinese stock market were transformed into 30-day-long sequences with 10 learning features and 3-day earning rate labeling. The model was fitted by training on 900,000 sequences and tested using another 311,361 sequences. In [\[11\]](#page-20-4), a CNN (convolutional neural network)–LSTM model is proposed to predict gas field production based on a gas field in southwest China. The CNN has a feature extraction ability, and LSTM can learn sequence dependence. By the combination of the two abilities, the CNN–LSTM model can describe the changing trend of gas field production. In [\[12\]](#page-20-5), augmentation of fully convolutional networks with LSTM–RNN (recurrent neural) submodules for time series classification is proposed. The proposed LSTM–FCN (fully convolutional network) achieves state-of-the-art performance compared with others. In [\[13\]](#page-20-6), a novel traffic forecast model is proposed based on an LSTM network. Differently from conventional forecast models, the proposed LSTM network considers temporal–spatial correlation in a traffic system via a two-dimensional network that is composed of many memory units. A comparison with other representative forecast models validated that the proposed LSTM network can achieve better performance. In [\[14\]](#page-20-7), a GRU network is proposed based on experience replay and the Snake Optimizer for real-time prediction in real-world non-stationary channels.

At present, there are relatively few studies on the prediction of carbon dioxide concentration in small layer houses in China. In addition, most existing studies rely on ingle-model prediction.

In this study, LSTM and GRU models with good prediction performance were constructed to predict the carbon dioxide concentration in a small layer house.

The second part of the paper introduces the acquisition of the datasets, the research of GRU and LSTM networks, and the construction of the prediction models. The third part draws the curve between the predicted and actual values of the model, draws the MAE and MSLE curves of the model prediction, and analyzes the performance of the GRU and LSTM models. The fourth part discusses the research of the paper. The fifth part is the conclusion of the paper.

2. Materials and Methods *2.1. Data Acquisition*

2.1. Data Acquisition The experiment was conducted in a layer house from January to December in 2023. In 2023, the December in 2023.

The experiment was conducted in a layer house from January to December in 2023. The selected experimental layer house was an intensive closed layer house. Each layer house was 100 m long, 15 m wide, and 4 m high, with five rows and four layers of cage equipment. The breed of the layers was Hailan grey, with a feeding density of 74 layers. per group, and the designed feeding capacity of a single building was 53,280 layers. The layer house utilized a combined positive and negative pressure ventilation system with a
designed of 95 fans with a model of 95 longitudinal design. The positive pressure ventilation system consisted of 95 fans with a
diameter of 300 cm each of 18 fans with and the negative pressure in 1990. diameter of 300 cm each, and the negative pressure ventilation system consisted of 18 fans with a diameter of 1400 cm each. The house was equipped with wet curtains, covering a $t_{\rm tot}$ total area of 119 m². The monitoring device consisted of a data acquisition node, master control module, and remote terminal management platform and continuously collected data from 00:00 to 24:00 every day. There were 12 devices in the layer house, from A data from 00:00 to 24:00 every day. There were 12 devices in the layer house, from A to M. $\frac{1}{2}$ to M. The laying hen house and the monitoring device in the layer house, home $\frac{1}{2}$ to M. The laying hen house and the monitoring device in the layer house are shown in Figures [1](#page-2-0) and [2.](#page-3-0) 1 and 2.

Figure 1. The on-site image of the measurement experiment in the layer house.

Figure 2. The temperature monitoring device in the laying hen house. The measurements lasted from May to June 2023. μ ay to June 2023.

2.2. Correlation Coefficient

The layer house $CO₂$ concentration exhibits time-series patterns and autocorrelation, that is, the data from the previous moment influences the current change of data [\[15\]](#page-20-8). Therefore, a model should not only consider the influence of real-time environmental factors but also the influence of historical data on the current moment $[16]$.

To improve the effectiveness of the model input information and reduce irrelevant noise interference, this study adopted the correlation coefficient to analyze the degree of noise influence of the factors on the layer house $CO₂$ concentration and selected the factors with high correlation as the model's inputs [\[17\]](#page-20-10). The correlation coefficients were calculated using Equation (1) . high correlation (1). The model is input single equation (1). *X X Y Y* ()()

$$
r = \frac{\sum\limits_{i=1}^{n} (X_i - \overline{X})(Y_i - \overline{Y})}{\sqrt{\sum\limits_{i=1}^{n} (X_i - \overline{X})^2} \sqrt{\sum\limits_{i=1}^{n} (Y_i - \overline{Y})^2}}
$$
(1)

duced into LSTM to record additional information. Input, output, and forget gates are included to control the memory [\[20\]](#page-20-13). Memory, referred to as a cell that has the same shape as in the hidden state, is intro-

2.3.1. Forget Gate

A forget gate decides the types of information that should be discarded or retained. The information from both the previous hidden state and the current input is simultaneously transmitted to a sigmoid function. The output value is between zero and one. The information should be discarded or retained when the output value is closer to zero or one, respectively [\[21\]](#page-20-14). The forget gate is shown in Equation (2).

$$
f_t = \sigma(x_t w_{xf} + h_{t-1} w_{hf} + b_f)
$$
\n⁽²⁾

2.3.2. Input Gate

An input gate is used to update the state of the cell. First, the information of the previous hidden state, *ht*−1, and the information of the current input, *X^t* , are transmitted to a sigmoid function [\[22\]](#page-20-15). The value is adjusted between zero and one to determine the types of information to be updated, with zero representing unimportant and one representing important information [\[23\]](#page-20-16). Second, *ht*−¹ and *X^t* are transmitted to a tanh function to create a vector with a new candidate value (candidate memory). Finally, the output value of the sigmoid function, It, is multiplied by the output value of the tanh function, which is the candidate memory [\[24\]](#page-20-17). The output value of the sigmoid function determines the types of information in the output value of the tanh function that are important and need to be retained $[25]$. The input gate is shown in Equation (3).

$$
i_t = \sigma(x_t w_{xi} + h_{t-1} w_{hi} + b_i)
$$
\n(3)

2.3.3. Output Gate

An output gate is used to determine the value of the next hidden state. A hidden state contains information from previous inputs [\[26\]](#page-20-19). First, h_{t-1} and X_t are transmitted to a sigmoid function; second, the new cell state, *C^t* , is transmitted to the tanh function [\[27\]](#page-20-20). Finally, the output of the tanh function is multiplied by the output of the sigmoid function, *Ot* , to determine the types of information that the hidden state should carry, *h^t* [\[28\]](#page-20-21). The hidden state is then used as the output of the current cell, transmitting *C^t* and the new hidden state, h_{t+1} , to the next time step [\[29\]](#page-20-22). The output gate is shown in Equation (4).

$$
o_t = \sigma(x_t w_{xo} + h_{t-1} w_{ho} + b_i)
$$
\n⁽⁴⁾

2.4. GRU

Gated recurrent neural networks are designed to better capture the dependencies of time series data with larger intervals. The GRU is a commonly used gated recurrent neural network [\[26\]](#page-20-19).

In the hidden layers of RNNs, the gradients of variables may vanish or explode. Although gradient clipping can cope with the exploding gradient problem, it cannot resolve the vanishing gradient problem. The GRU, similar to LSTM, was developed to overcome problems such as the gradient in long-term memory and backpropagation [\[30\]](#page-20-23).

The input and output structures of a GRU are the same as those of a regular RNN. The input includes both the input at moment *t*, *x^t* , and the hidden layer state at moment *t* − 1, *h*_{t−1}, which contain the information about the previous node. The output includes the output of the hidden node at moment *t*, *yt* , and the hidden state to be transmitted to the next node, *h^t* [\[31\]](#page-20-24).

Unlike LSTM, which has three gates, GRU has only two gates, which are the reset and update gates. The states of the two gates are obtained from the previous transmitted state, *h*_{*t*−1}, and the input of the current node, *X*^{*t*} [\[32\]](#page-20-25). A graphical representation of the structure of a GRU is shown in Figure [6.](#page-6-0)

Figure 6. Graphical representation of the structure of a GRU. **Figure 6.** Graphical representation of the structure of a GRU.

2.4.1. Update Gate 2.4.1. Update Gate

An update gate, *rt*, is used to control the extent to which the state information from An update gate, *rt* , is used to control the extent to which the state information from the previous moment is applied in the current state, with more state information being used from the previous moment as the update gate value increases. The information from the previous and current moments is right-multiplied by a weight matrix. Subsequently, the summed data are fed into the update gate and multiplied by a sigmoid function to yield a value between zero and one [\[33\]](#page-21-0). The update gate is shown in Equations (5) and (6) .

$$
r_t = \sigma(w_r \cdot [h_{t-1}, x_t]) \tag{5}
$$

$$
\widetilde{h}_t = \tanh(w \cdot [r_t * h_{t-1}, x_t]) \tag{6}
$$

2.4.2. Reset Gate

state is written to the current candidate set, with less information from the previous state written as the reset gate value decreases [\[34\]](#page-21-1). The data processing of the reset gate is the same as that of the update gate, where the information from the previous and current
same as that of the update gate, where the information from the previous and current into the reset gate and multiplied by a sigmoid function to yield a value between zero and into the reset gate and multiplied by a sigmoid function to yield a value between zero and same as that of the update gate, where the information from the previous and current one. The differences between the two weight matrices are their values and purposes [\[19\]](#page-20-12).
The great arts is ab sum in Equations (7) and (8). The reset gate is shown in Equations (7) and (8) . A reset gate, *zt* , is used to control how much historical information from the previous moments is right-multiplied by a weight matrix. Subsequently, the summed data are fed

$$
z_t = \sigma(w_z \cdot [h_{t-1}, x_t]) \tag{7}
$$

$$
h_t = (1 - z_t) * h_{t-1} + z_t * \widetilde{h}_t
$$

Table 2. Hyperparameters for the GRU and LSTM models.

(8) Hyperparameter optimization

This study applied the adaptive learning rate algorithm as Adam.

(9) Network training

The mean absolute error (MAE) between the predicted and label values was used as the loss function, and the mean squared logarithmic error (MSLE) was used as a metric for monitoring the networks. The MAE and MSLE were retained for each iteration during training. Early Stopping, a simple and effective method for avoiding overfitting, was used during model training. It works by monitoring the validation set performance during model training and stopping the training when the validation set performance is optimal, which can determine appropriate training rounds and avoid overfitting effectively.

(10) Inspecting training process information

For each iteration, the loss and monitoring metrics for both the training and validation sets were plotted.

(11) Forecasting

The evaluate (\cdot) function was used to calculate the loss and monitoring metrics for the entire test set to obtain a timescale for each true value. The GRU and LSTM models' prediction flow is shown in Figure [9.](#page-10-0)

Figure 9. The experimental procedure of this study to develop the GRU and LSTM models. **Figure 9.** The experimental procedure of this study to develop the GRU and LSTM models.

3. Results 3. Results

3.1. Evaluation Indicators 3.1. Evaluation Indicators

To evaluate the performance and assess the reliability of the models after training To evaluate the performance and assess the reliability of the models after training was completed, the input factors of the validation set were fed into the trained model to get the predicted values. These predictions were then compared to the actual observed values. Mean absolute error (MAE) between the predicted and label values was used as the loss function, and mean squared logarithmic error (MSLE) was used as a metric for monitoring the networks.

MSLE is the indicator used to evaluate the prediction model. It is the average value MSLE is the indicator used to evaluate the prediction model. It is the average value of logarithmic error, which can be used to measure the prediction ability of the model for data with large values. MSLE is calculated as shown in Equation (9).

$$
MSE = \frac{1}{N} \sum \left[\log(y_i + 1) - \log(\hat{y}_i + 1) \right]^2
$$
 (9)

The range of $m_{\text{H}} \approx 0$, with 0 indicating a perfect model where the predicted m_{H} value matches the true value exactly. The larger the error, the larger the MAE value. MAE
is shown in Equation (10) is shown in Equation (10). is shown in Equation (10). The range of MAE is $(0, +\infty)$, with 0 indicating a perfect model where the predicted

$$
MAE = \frac{1}{N} \sum_{i=1}^{N} |\hat{y}_i - y_i|
$$
 (10)

3.2. Predictive Evaluation 3.2. Predictive Evaluation

The sample sizes of the test sets were 5000–20,000, and the predicted and actual values are shown in Figure [10.](#page-11-0)

Figure 10. Comparison of predicted and actual values with the GRU and LSTM models. **Figure 10.** Comparison of predicted and actual values with the GRU and LSTM models.

It can be seen from Figure [10](#page-11-0) that when the number of datasets put into the GRU model was increased from 5000 to 15,000, the agreement between the predicted and actual model was increased from 5000 to 15,000, the agreement between the predicted and actual values gradually increased. When 20,000 datasets were put into the GRU model, the degree gree of agreement between the predicted and actual values slightly decreased. We conof agreement between the predicted and actual values slightly decreased. We concluded It can be seen from Figure 10 that when the number of datasets put into the number of datasets put into the GRU

that when the number of datasets put into the GRU model was within an appropriate range, the predication accuracy increased with the number of datasets.

When the number of datasets input to the LSTM model was increased from 5000 to 20,000, the agreement between the predicted and actual values gradually increased. 20,000, the agreement between the predicted and actual values gradually increased.

3.3. Evaluation of Model Performance by Plotting Training and Validation Loss Curves 3.3. Evaluation of Model Performance by Plotting Training and Validation Loss Curves

The training and validation loss curves are two evaluation metrics commonly used in the deep learning training process to represent the errors of a model during training and validation.

3.3.1. The Train_Loss and Train_Msle of the GRU Model and LSTM Model 3.3.1. The Train_Loss and Train_Msle of the GRU Model and LSTM Model

Training loss refers to the model's error on the training set, indicating the magnitude Training loss refers to the model's error on the training set, indicating the magnitude of the model's prediction error on the training samples during the training process. of the model's prediction error on the training samples during the training process. The train_loss of the GRU and LSTM models is shown in Figure [11.](#page-12-0) The train_loss of the GRU and LSTM models is shown in Figure 11.

Figure 11. The train_loss of the GRU and LSTM models. **Figure 11.** The train_loss of the GRU and LSTM models.

It can be seen from Figure [11](#page-12-0) that when 5000 datasets were put into the models, the training_loss curve of the GRU model showed that the training error stayed at the maximum for one training quale, whereas the curve of the LSTM model rapidly decreased after the curve of the LSTM model rapidly decreased at the curve of the LSTM model rapidly decreased maximum for one training cycle, whereas the curve of the LSTM model rapidly decreased

after training started. During model training, the validation set was used to test the performance of the models at regular intervals to obtain the val_loss results. after training started. During model training, the validation

The training_loss of the GRU and LSTM models gradually decreased as the number of training sessions gradually increased. The models produced more accurate predictions on the training samples because they had learned more features and patterns. Therefore, the training_loss curve showed a decreasing trend as the number of training sessions increased.

The train_msle of the GRU and LSTM models is shown in Figure [12.](#page-13-0) The train_msle of the GRU and LSTM models is shown in Figure 12.

Figure 15. Five-Fold cross-validation to check for overfitting. **Figure 15.** Five-Fold cross-validation to check for overfitting.

A comparison was made between the train_loss and val_loss of the LSTM model and the GRU model to determine if there was overfitting in the model. The comparison results are shown in Table [3.](#page-16-0)

Table 3. Comparison of training error and testing error.

It can be seen from Table [3](#page-16-0) that when the train_loss of the LSTM model and GRU decreased, val_loss also decreased, and there was no overfitting in the model.

3.3.4. Model Application

A comparative field test for the prediction model was conducted in an experimental layer house, in where the actual $CO₂$ concentration in the layer house was used as the model input to predict the $CO₂$ concentration after one minute.

The predicted and actual values of the $CO₂$ concentration were considered as the basis for the ventilation of the layer house, and the upper limit of $CO₂$ concentration was set as 500 ppm.

If the predicted value of the $CO₂$ concentration was used as the basis for ventilation, the fan was turned on when the predicted value reached 500 ppm.

If the actual value of the $CO₂$ concentration was used as the basis for ventilation, the fan was turned on when the actual value reached 500 ppm.

The $CO₂$ concentration and fan status of the layer house in both cases are shown in Table [4.](#page-16-1)

Table 4 shows that if the predicted value was used as the basis, at 9:11:40, the predicted and actual values were 500.0410 ppm and 499.9687, respectively, and the fan was turned on. At 09:11:55, the actual value was 499.2547 ppm, and the fan was turned off. the fan was turned off.

If the actual value was used as the basis, when the actual value was 500.1364 ppm, the fan was turned on. At 09:12:00, the actual CO₂ concentration was 499.3159 ppm, and the fan was turned off.

It could be judged from the experimental results that if the predicted value was used as the basis for ventilation, the $CO₂$ concentration in the layer house could be ensured to remain below the limit value at all times, and the total operation time of the fan was 15 s.

If the actual value was used as the basis for ventilation, the $CO₂$ concentration exceeded It the limit value for 10 s after starting the fan, and the total operation time of the fan was 20 s.

This concludes that using the predicted value as the basis for adjusting the operating
This concludes that using the predicted value as the basis for adjusting the operating status of fans could reduce the CO₂ concentration faster and ensure the constraints of the $CO₂$ concentration in the chicken house. **4. Discussion**

4. Discussion \blacksquare is calculated 10 that when the number of datasets of the number of datasets of the GRU and LSTMM and LST

It can be seen from Figure 10 that when the number of datasets of the GRU and LSTM models gradually increased, the agreement of the predicted and actual values gradually increased. increased. However, when the number of datasets reached 20,000, the agreement of the pre-

However, when the number of datasets reached 20,000, the agreement of the predicted and actual values of the GRU model decreased, while the agreement of the LSTM model did not decrease.

It could be concluded that the model had optimal datasets. When the number of $\overline{}$ datasets was within the optimal range, the agreement of the predicted and actual values tasets was within the optimal range, the agreement of the predicted and actual values increased with number of datasets. When the number of datasets exceeded the optimal increased with number of datasets. When the number of datasets exceeded the optimal range, the agreement of the predicted and actual values was uncertain. range, the agreement of the predicted and actual values was uncertain.

In order to acquire the optimal number of datasets, prediction was attempted with 15,000 to 20,000 datasets, with 1000 datasets added each time. 15,000 to 20,000 datasets, with 1000 datasets added each time.

The MAE of the GRU and LSTM is shown in Figure [16.](#page-17-0) The MAE of the GRU and LSTM is shown in Figure 16.

Figure 16. *Cont*.

Figure 16. Loss of the GRU and LSTM models within 15,000 to 20,000 datasets. **Figure 16.** Loss of the GRU and LSTM models within 15,000 to 20,000 datasets.

It can be seen from Figure 1[6 th](#page-17-0)at when the number of datasets was between 15,000 It can be seen from Figure 16 that when the number of datasets was between 15,000 and 17,000, the prediction loss of the GRU model decreased with the increase of the number of datasets. When the number of datasets exceeded 17,000, the agreement between the predicted and actual values was uncertain. It could be concluded that the optimal number predicted and actual values was uncertain. It could be concluded that the optimal number of datasets for the GRU model was between 15,000 and 17,000. When the number of datasets for the GRU model was between 15,000 and 17,000. When the number of tasets was between 15,000 and 20,000, the prediction loss of the LSTM model decreased with increasing number of datasets, and the agreement between the predicted and real with increasing number of datasets, and the agreement between the predicted and real values was certain. It could be concluded that the optimal number of datasets for the LSTM values was certain. It could be concluded that the optimal number of datasets for the second that the optimal number of ϵ datasets was between 15,000 and 20,000, the prediction loss of the LSTM model decreased

It can be seen from Figures $11-14$ $11-14$ that compared with those of the GRU model, the LSTM model has more stable but lower prediction speed and more loss. The reason was that the two models had different structures. The LSTM model contained three gates the, forget gate, the input gate, and the output gate, and the LSTM model had more parameters. The GRU model contained two gates, the update gate and the reset gate. Due to the structure of the model, the stability of the LSTM model was higher than that of the GRU model, and the prediction accuracy and speed were lower than those of the GRU model.

The loss of the GRU model was 70.8077 to 126.7029 ppm, and the loss of LSTM model was 78.8596 to 136.0896 ppm. The prediction time of the GRU model was 16 to 24 ms, and the prediction time of the LSTM model was 17 to 26 ms.

When the model was applied in a layer house, the measured value of the carbon dioxide concentration in the house was used as the input, which required high accuracy

5. Conclusions

- els in predicting environmental parameters, specifically the CO₂ concentration in a layer house, provided significant insights and contributions to the field of predictive modeling for agricultural and environmental applications. (1) In this study, an extensive examination of the performance of GRU and LSTM mod-
- (2) According to the correlation coefficients, the layer house temperature, humidity, and $CO₂$ concentration were selected as the feature data, and a model for predicting the CO_2 concentration in a layer house was constructed based on the GRU and LSTM.
- (3) Different datasets were selected, and the corresponding prediction results were obtained. The training and validation errors of the GRU and LSTM models were analyzed. The results showed that there was an optimal range of the number of datasets for the prediction model, and the loss of the model was minimal within this range
- (4) MAE between the predicted and label values was used as the loss function, and MSLE was used as a metric for monitoring the networks. MAE and MSLE were retained for each iteration during training. For each iteration, the loss and monitoring metrics of both the training set and validation set were plotted. The evaluate (\cdot) function was used to calculate the loss and monitoring metrics for the entire test set to obtain a timescale for each true value.
- (5) While increasing the dataset size yielded an improvement in prediction accuracy for both GRU and LSTM models, the findings noted a decline in prediction accuracy for the GRU model when 20,000 datasets were utilized. This suggests that the GRU model's performance might plateau or decline beyond a certain dataset threshold, indicating a limitation in handling larger datasets. We will focus on solving this problem in future work.
- (6) The datasets for this study were collected between June and July 2023. In future research, the collection time of the datasets will be extended to four seasons to improve the applicability and robustness of the model.
- (7) This study will address the computational efficiency issue of the model in future work.
