Abstract: There have been manifold thrilling studies strikingly conducted in recent years to explore factors influencing student acceptance of massive open online courses (MOOCs). The principal goal was to determine future prediction and sustainable use of MOOCs for providing pervasive quality education services. This has led to the examination of different theoretical models tested on varying sample sizes for factor exploration. However, existing studies have reflected heterogeneous results caused by divergent sources not observed in the literature using the multiple correspondence analysis (MCA). This study aimed to apply the data science method of MCA to explore hidden associations amongst factors influencing student acceptance of MOOCs and heterogeneity sources of theoretical models and sample sizes to blur the literature hiatus. Results based on data extracted from 54 primary studies published from 2015 to 2021 with a total of 19,638 valid student responses generally conclude the existence of four main levels of associations. The four associations were respectively composed of single, blended, extended and complex theories and each level is associated with distinct categories and a combination cloud of similar categories. Moreover, results indicated that very small sample size is the most unusual under the basic assumption that none of the variables are correlated. It is practically germane to confirm hidden associations in a dataset of influencing factors to help reach a much greater understanding of the application and performance of MOOCs for sustainable education services.

**Keywords:** burt matrix; indicator matrix; multiple correspondences; online course; sample size; technology acceptance; theoretical model

# 1. Introduction

The technology of massive open online courses (MOOCs) has become a recent educational innovation for sustainable online education services that have gained widespread popularity across the world [1]. MOOCs have been described as online distance-learning courses that provide free educational resources to registered students in various disciplines [2]. MOOC is generally recognized as one of the most recent developmental phases of open educational resources that have tremendously transformed higher education institutions and significantly minimized the spiraling costs of learning. It is reshaping the quality of teaching and learning experiences for students and it provides a wide diversity of high-quality courses and valuable learning materials for the diverse needs of students [3]. It can motivate students for learning [4], allow for free sharing of learning materials [5], support interactivity with the aid of various communication tools and provide numerous opportunities for students to seamlessly collaborate [6]. The use of MOOCs can provide students with pervasive access to a diverse spectrum of learning resources, thereby promoting student-centered instructions [7]. MOOC can improve the quality of learning pedagogy, help accelerate collaboration, ensure social cohesion and promote sustainable development growth [8,9].

However, it comes naturally with some inherent challenges despite its rapid development and numerous intrinsic benefits. The challenges include lack of standardization and flexibility [10], incapacity to provide real-time feedback to students [5], inability to obtain sustainable financial revenue [6] and inadequate learning time for students [11]. In addition, it is difficult to implement a teaching process affording the specific characters of students using MOOCs because of a huge number of participants and the teacher cannot identify the characters of individual students through face-to-face interaction [12]. These challenges have contributed to a low degree of student participation after enrolment in MOOCs [1,13,14] and acceptance rates by students are universally low [15,16]. The average completion rate of MOOCs is less than ten percent and the dropout rate is generally very high [6]. The situation can lead to uncertainty regarding the efficacy, sustainability and performance of MOOC as a learning platform [7]. Moreover, scholars have ascribed the dropout rates of MOOCs to inadequate control of a learning environment, lack of background knowledge and skills, conflict in a discussion forum among students and the feeling of complete isolation [11,17]. However, there has been a contention that the success of MOOCs should not be solely evaluated by course completion and drop-out rates because students enroll for various motives. They may, for instance, enroll to satisfy their curiosity, advance their careers, plan for the future, acquire skills and connect with people to improve knowledge without intending to finish the entire course [3,5,18]. Moreover, scholars have espoused that the success of MOOCs should rather be based on the learning behaviors of students such as their acceptance [3,19,20]. This proposition makes it propitious to investigate factors influencing student acceptance of MOOCs.

Different studies have used diverse theoretical models, sample sizes and analysis methods to expose numerous significant factors influencing student acceptance of MOOCs [1,21]. MOOC was proposed as a form of sustainable higher education by exploring the theory of task-technology fit (TTF) and technology acceptance model (TAM) to create a novel paradigm of education [22]. However, no consensus has been generally reached as to which factors best influence student acceptance of MOOCs. The one reason for the lack of consensus may be the curb of the existing studies in examining other salient determinants through the exploration of associations that remains a gap in the literature. It has been demonstrated through meta-analysis research that theoretical models and sample sizes are the significant sources of heterogeneity in factors influencing student acceptance of MOOCs [23]. The practical implications of utilizing an appropriate sample size [24] and relevant theory [25] in research are widely appreciated. The cardinal objective of this study was to apply multiple correspondence analysis (MCA) to examine associations among factors influencing student acceptance of MOOCs and heterogeneity sources of theoretical models and sample sizes. The unique contributions of this study to the body of knowledge and practice are three-fold as explicated below.

- 1. A comprehensive review of the related studies on factors influencing student acceptance of MOOCs.
- 2. The extraction of useful qualitative data from the reviewed studies in a format suitable for advanced statistical analysis.
- 3. The application of MCA to expose hidden associations in the extracted qualitative data to help improve the understanding of student acceptance of MOOCs.

The remainder of this paper is succinctly organized as follows. Section 2 describes the research methods and materials. Section 3 presents the study results. Section 4 discusses the study results. The paper is ultimately concluded in Section 5 with a brief remark.

#### 2. Materials and Methods

MCA is an exploratory data science method for discovering geometrical representations of categorical data in multiple dimensional spaces [26]. The present study uses the method to explore the geometrical representation of the data associated with factors influencing student acceptance of MOOCs and sources of heterogeneity. The study methods present three phases based on literature review, data codification and data analysis.

#### 2.1. Literature Review

A literature search was executed with the support of the widely used scholastic databases of Scopus, Web of Science and Google Scholar to retrieve pertinent quantitative studies. The search parameters were based on simple keywords of the form "MOOC acceptance" and "Factors of MOOC acceptance" to focus the searching within each database. The studies should intrinsically contain useful information to be declared pertinent to this study. The useful information includes the authors of a study, year of publication, country of study, student sample, a most significant factor, path coefficient analysis, the acceptance behavior of students, method of data analysis and the theoretical model of factor exploration. Different studies have tested the strengths of numerous theoretical models on various sample sizes to expose factors influencing student acceptance of MOOCs. The theoretical models so far reported in the literature for this purpose can be categorized into four groups of single, blended, extended and complex theories. The category of single models is made up of studies that have used the basic information system theories for factor exploration. The blended model agglutinates two or more basic theories to explain factors influencing student acceptance of MOOCs. The extended model incorporates other useful factors into a single model while the complex model integrates other factors into a blended model. The basic theories include student online learning readiness (SOLR) [27], unified theory of acceptance and use of technology (UTAUT) [28], uses and gratification theory (UGT) [29], expectation-confirmation model (ECM) [30], theory of consumption value (TCV) [31], theory of task-technology fit (TTF) [32], distance learning theory (DLT) [33], technology user environment (TUE) [34], self-efficacy theory (SET) [35], stimulus organism response model (SORM) [36], Triandis model (TRAM) [37], technology acceptance model (TAM) [38], attachment theory (ATT) [39], social technical system theory (STST) [40], selfregulation theory (SRT) [41], self-determination theory (SDT) [42,43], social cognitive theory (SCT) [44], theory of planned behavior (TPB) [45], theory of information systems success (ISS) [46], subjective task value theory (STVT) [47] and service quality (SERVQUAL) [48].

Different authors have used single theories to investigate factors influencing student acceptance of MOOCs. SOLR was used to predict communication competency, self-management of learning, social competency and technological competency as factors influencing student readiness to accept MOOCs [4]. The same theory was used to identify computer self-efficacy as the most significant factor predicting student readiness for MOOCs [49]. UTAUT was used to show that performance expectancy, effort expectancy, social influence and facilitating conditions are significant factors influencing the behavioral intention of students to use MOOCs [50]. The same theory was applied to report that behavioral intention has a significant effect on student usage of MOOCs [51]. UGT was applied to show that openness, subjective norms, student satisfaction and performance expectancy are significant factors influencing the continuance intention of students to use MOOCs [7]. ECM was used to identify perceived usefulness and student satisfaction as the significant factors influencing the continuance intention of students to use MOOCs [52]. The same theory was used to reveal student satisfaction as the most significant factor of continuance intention to use MOOCs [53]. TCV was tested to discover perceived functional value as the most significant factor influencing the continuance intention of students to use MOOCs [54]. TTF was applied to discover vividness of course content, teacher knowledge and interactivity as significant factors influencing the behavioral intention of students to use MOOCs [55]. DLT was applied to show that intellectual capital is the strongest determinant of the behavioral intention of students to use MOOCs [20]. TUE was developed to show that self-regulation, perceived usefulness, performance-to-cost value, lack of accessibility, tradition and social norms and lack of information significantly influenced the intention of students to adopt MOOCs [34]. SET was adapted to show that perceived usefulness and perceived enjoyment are significant factors influencing the continuance intention of students to use MOOCs [56]. The authors in [14] drew upon the SORM to demonstrate that engagement on platform significantly influenced the continuance intention of students to

use MOOCs. TRAM was used to show that behavioral intention and facilitating conditions are significant factors influencing the actual usage of MOOCs by students [6].

Many extant studies have mainly blended TAM, ECM, TPB, ISS and SDT with other theories for factor exploration. They include the blending of TAM and IDT to discover student attitude as the most significant factor of MOOC usage intention [10]. TAM and UTAUT exposed performance expectancy, effort expectancy, social influence, computer self-efficacy, student attitude and facilitating conditions as significant factors of student acceptance of MOOCs [15]. TAM and SST unveiled student attitude, perceived convenience and perceived gain as significant factors of MOOC usage intention [57]. TAM and ISS revealed course quality and perceived usefulness as significant factors of continuance intention of students to use MOOCs [58]. TAM and TPB divulged behavioral intention, perceived behavioral control and subjective norms as significant factors of MOOC usage by students [59]. TAM and SCT disclosed perceived ease of use and perceived usefulness as significant factors influencing continuance intention of students to use MOOCs [1]. TAM, ECM and SDT unveiled student satisfaction as the most significant factor influencing continuance intention to use MOOCs [19]. TAM, SDT and SERVQUAL exposed student satisfaction and autonomous motivation as significant factors influencing the behavioral intention to use MOOCs [60]. ECM and TTF revealed perceived usefulness and student satisfaction as significant factors influencing continuance intention to use MOOCs [61]. ECM and STV unveiled intrinsic value, utility value, anxiety and risk of arbitrary learning as significant factors influencing the continuance intention of students to use MOOCs [62]. ECM and SET were used to demonstrate that continuous learning willingness was significantly influenced by self-efficacy and student satisfaction with MOOCs [63]. SDT and TPB revealed student attitude and perceived behavioral control as significant factors of behavioral intention to use MOOCs [64]. SDT and SRT unveiled intrinsic motivation and conscientiousness as significant factors influencing the continuance intention of students to use MOOCs [65]. SDT and TUE disclosed intrinsic motivation, social recognition, perceived value and perceived usefulness as significant factors of the behavioral intention of students to adopt MOOCs [3]. ATT and STST unveiled functional attachment and emotional attachment as significant factors of continuance intention of students to use MOOCs [66].

The widely used TAM, UTAUT and ECM theories among others have been extended with the incorporation of supplementary factors by different authors. TAM was tested with computer self-efficacy, perceived convenience, learning tradition and self-regulated learning to predict the behavioral intention of students to adopt MOOCs [2]. It was used with knowledge access, knowledge storage, knowledge application and knowledge sharing to predict student acceptance of MOOCs [5]. It was applied with coercive pressures, mimetic pressures and normative pressures to examine the adoption of MOOCs by students [67]. It was validated with social influence, course quality, collaboration and perceived enjoyment to predict the behavioral intention of students to use MOOCs [68]. It was applied with perceived quality, perceived enjoyment and usability to investigate factors influencing the effective use of MOOCs by students [13]. It was tested with the perception of time to explore factors influencing student acceptance of MOOCs [11]. It was used with reputation, student habit, subjective norm and conformity tendency to examine factors influencing behavioral intention to use MOOCs [69]. It was corroborated with perceived learner control, electronic learning self-efficacy and personal innovativeness to examine factors influencing the behavioral intention of students to adopt MOOCs [70].

UTAUT was used with student attitude and computer self-efficacy to identify factors influencing student usage of MOOCs [16]. It was tested with instructional quality, computer self-efficacy and service quality to investigate factors influencing student usage of MOOCs [18]. It was applied with web quality and self-efficacy to examine factors influencing the behavioral intention of students to use MOOCs [71]. It was corroborated with motivation, course design, interest, course delivery, media, interactivity and assessment to investigate factors influencing student usage of MOOCs [72]. It was used with perceived value to examine factors influencing student adoption of MOOCs [73]. It was validated with perceived course quality and perceived satisfaction to predict student usage of MOOCs in the regime of coronavirus pandemic [74].

ECM was used with curriculum organization, video quality, learning evaluation, learning analysis and socialized interaction to explore factors influencing the continuance intention of students to use MOOCs [75]. It was applied with knowledge outcome, performance proficiency and social influence to investigate factors influencing the continuance intention of students to use MOOCs [76]. It was tested with perceived reputation, perceived openness and perceived enjoyment to discover factors influencing the continuance intention of students to use MOOCs [77]. It was validated with task technology fit to explore factors influencing the continuance intention of students to use MOOCs [77]. It was validated with task technology fit to explore factors influencing the continuance intention of students to use MOOCs [78]. It was extended with attitude and curiosity to discover that the continuance intention of students to use MOOCs was significantly influenced by attitude and curiosity [79]. SORM was extended with the features of technological and environmental to discover that flow experience is a significant factor influencing the continuance intention of students to use MOOCs [80].

The complex model has recorded a few studies that have investigated the extension of blended theories for factor exploration. ECM and TAM with the factors of MOOC performance and student habit were used to understand the psychological processes underlying the continuance intention of students to participate in MOOCs [81]. TTF and SDT with social motivation were used to examine factors influencing student adoption of MOOCs [21]. UTAUT and TTF with student satisfaction were used to explore factors influencing the continuance intention of students to use MOOCs [82]. TAM and TTF with social motivation and MOOC features were used to investigate the continuance intention of students to use MOOCs [83]. In a study of MOOC performance, the modified ISS and ECM with gamification perception were combined to indicate that perceived usefulness, student satisfaction and gamification perception significantly influenced the continuance intention of students to use MOOCs [84].

The comprehensive review of literature has shown the dearth of research on the application of MCA to explore associations among factors influencing student acceptance of MOOCs and heterogeneity sources. Table 1 summarizes the characteristics of data extracted from the 54 reviewed articles based on the variables of authors of an article (author), year of article publication (year), country of study (country), sample size (sample), most significantly influencing factors (factor), path coefficient (path), type of MOOC acceptance behavior (accept), data analysis method (method) and theoretical model applied for factor exploration (theory). An inclusive review of 54 studies on factors influencing student acceptance of MOOCs across 14 different countries of the world has been conducted to harvest pertinent data. This approach of soliciting research data from the published articles has been judged to be novel for obtaining reliable and validated scientific evidence in a format that is readily amenable to MCA [85].

The data in Table 1 show that about 40.74% of the studies were conducted in China, followed by Malaysia (14.81%) and Taiwan (7.41%). The same volume of works was recorded by South Korea, Australia and India (5.56%), Spain, Jordan and Saudi Arabia (3.70%) while the same volume of works was recorded by Turkey, Brazil, Ghana, Pakistan and Iran (1.85%). The sample size of respondents across studies ranged from 101 to 1344 with a mean of 360.70, a standard deviation of 243.33 and a total of 19,638 students. There are 28 significant factors identified across the 54 studies with the most significant one selected per study. The most significant factor has the highest path coefficient [23] and path coefficient (path) scores vary from 0.222 to 0.861. Structural analysis tools allow for the estimate of complex causal relationships among factors to test the path coefficients for statistical significance [86]. Four categories of MOOC acceptance behaviors (accept) were identified from the literature review as continual, intention, readiness and usage. The data analysis methods were mainly structural equation modeling (SEM), multiple regression analysis (MRA) and hierarchical regression analysis (HRA) as indicated by the

# method variable. The theoretical models are indicated by the theory variable as previously delineated.

# 2.2. Data Codification

The data for this study were extracted from 54 reviewed articles on factors influencing student acceptance of MOOCs (Table 1). The qualitative data for the MCA was coded as a subset of the characteristics of the extracted data. The variables used in the MCA are theory, sample and factor. The theory variable presents 4 categories coded as 1, 2, 3 and 4 for single, blended, extended and complex theories respectively. The sample variable presents

4 categories that were coded as 1, 2, 3 and 4 for a study with 101 to 411, 412 to 722, 723 to 1033 and 1034 to 1344 student participants to denote very small, small, large and very large samples respectively. The factor variable has 28 categories coded as 1, 2, ..., 28. The variables of theory and sample were found in a meta-analysis study to be the significant sources of heterogeneity effects, but year, country and type were not [23]. Heterogeneity refers to the variation in the outcome of a research and it can determine the difficulty in drawing valid conclusions [87]. Moreover, it can help reach a much greater understanding of factors influencing student acceptance of MOOCs. Table 2 shows the labels, categories and definitions of variable categories of influencing factors and heterogeneity sources.

Label is the unique identifier for a category.

#### 2.3. Data Analysis

The variables of theory, sample and factor pertinent to this study were captured in a dataset of influencing factors and heterogeneity sources (Table 1) to focus on a meaningful analysis that is consistent with MCA. The analysis of the subset of the dataset of influencing factors and heterogeneity sources was performed using the MCA to explore hidden associations. In more detail, MCA is an extension of the correspondence analysis (CA) to multiple variables, a generalization of the principal component analysis (PCA) to analyze manifold categorical variables and display hidden associations among categorical variables, or observations. It applies to qualitative variables in a similar way that PCA is amenable to quantitative variables. It finds the eigenvalue decomposition of the normalized covariance matrix of observations with the associated variables [91]. The method works by performing a series of mathematical transformations to compute the principal coordinates of the variable categories and observations in an optimal representation space based on inertia or eigenvalue criterion. The inertia in MCA is related to the eigenvalue in the parlance of PCA that measures how much categorical information is accounted for by each principal dimension. The higher the eigenvalue, the larger the amount of the total variance amongst categorical variables on that principal dimension [92].

MCA is a correspondence analysis performed on an indicator matrix or a Burt matrix with both matrices central to the analysis. The indicator matrix displays all observations in the form of a disjunctive map of variables. Each indicator variable along the matrix column represents one level of a categorical variable. Each observation along with the matrix takes a binary score of 1 or 0 depending on whether it does or does not belong to the category. The Burt matrix is a square symmetric map consisting of all cross-tabulations for all combinations of variables. It is more efficient than the indicator matrix for eigenvalue decomposition because its dimensions depend on the number of variable categories and not on the number of observations as in the case of the indicator matrix. It is a useful device for visualizing and analyzing the associations among categorical variables because it contains the counts of co-occurrences for all combinations of categories. The solutions computed by the method can be described by a bi-dimensional or biplot that plots most of the variable categories close together with unassociated ones plotted far apart [92].

The biplot graphical representation makes it easy to perceive, summarize, visualize and interpret a large complex dataset of categorical variables. It simplifies the structure of the inherent associations amongst variable categories and observations. The variable categories are data points on the graph such that categories close to the mean value are plotted near the graph origin and those that are more distant are plotted farther away from the origin. The variable categories with a similar distribution are close to each other through the formation of combination clouds of points [92,93]. The categories with different distributions are plotted at some distance apart and the resulting dimensions are interpreted by the locations of the points on the graph. The loadings of the points over the dimensions are important indicators. However, in general, a biplot is insufficient to explain most of the variances, but the first two dimensions usually contain higher eigenvalues than others [92,94].

MCA can be interpreted using two strategies which are factor analytical and cluster analytical [26]. In factor analytical strategy, one tries to label the principal dimensions, while clusters of categories are found using the cluster analytical strategy. This study follows the direction of factor analytical strategy using the materials provided by the MultipleCar toolbox [91] and the MCORRAN2 Matlab code [95]. The MCORRAN2 was used to generate the discrimination measures of the variable categories, while the MultipleCar toolbox was applied for other computations. A toolbox is a general software suitable for computing correspondence analysis with the aid of a graphical user interface [91]. The rotation of principal coordinates was performed using the widely known varimax orthogonal transformation to maximize the simplicity of interpretations of principal dimensions. The weighted scheme with default parameter was used to give an impressive Bentler simplicity index after rotation [96]. The simplicity indices of the principal coordinates of variables and principal coordinates of observations before rotation were 0.021 and 0.011 respectively. These simplicity indices of principal coordinates of variables and observations were increased to 0.901 and 0.874 respectively after rotation. This result implies that simplified principal coordinates of variables and observations were obtained using the varimax rotation algorithm with default parameter setting.

# 3. Results

MCA locates the variable categories in Euclidean space and the principal inertia is usually expressed as a percentage of the total inertia. The inertia values quantify the amount of variation that is accounted for by the corresponding principal dimensions. The higher the inertia, the larger the amount of the total variance among the variables on that principal dimension. Table 3 shows the result of the adjusted principal inertias based on the eigenvalues of the Burt matrix of non-trivial inertias, and cumulative inertia. The total inertia is 0.924, total principal inertia is 81.800% and cumulative inertia is 81.800%. The core bottleneck of inertias of dimensions is that they depend on the degree of associations among variable categories and can be seriously inflated. The previous study has suggested an adjusted version of inertia that was inspired by the joint correspondence analysis (JCA) to allow for higher and more meaningful percentages for the maps [97]. The average adjusted explained variance is 4.3%, which suggests that dimensions explaining less variance should be excluded from the map. This rule is equivalent to the criterion of one-eigenvalue of Kaiser's rule in exploratory factor analysis [91]. This study, therefore, found 5 dimensions or axes that explained 81.800% of the total inertia based on the adjusted inertia.

21	0.0000	0.0	81.8
22	0.0000	0.0	81.8

Total eigenvalue = 0.924, cumulative percentage = 81.800%.

The scree plot of eigenvalues against the number of principal dimensions is shown in Figure 1. The plot is generally used to visually determine the number of dimensions to retain in the MCA. The elbow of the plot, according to the scree test is where the eigenvalues tend to level off, which is 6 in this scenario. The significant number of dimensions to retain is therefore 5 to the left of the elbow to further confirm visually that 5 dimensions should be retained for the subsequent MCA analysis.

Figure 1. Scree plot of eigenvalues against the number of dimensions.

The MCA faithfully analyzed a total of 3 variables, 36 corresponding variable categories and 54 observations to give an overall solution with 22 dimensions (Table 3). The indices of associations are total inertia of 11.000 and Cramer's V statistic of 0.561 to indicate that 5 dimensions provide a satisfactory model fit with large association effects [98]. Moreover, the result shows the decomposition of total inertia into 22 axes to explain the total inertia of 0.924. The first, second, third, fourth and fifth dimensions accounted for 31.600%, 20.000%, 17.000%, 7.700%, 5.000%, respectively and together they accounted for 81.800% of the total inertia. The specification of the 5 dimensions is therefore sufficient for the MCA analysis because they account for a high proportion of the total inertia.

Table 4 shows the descriptive statistical result of variable categories by frequency, percentage and mass. The extended theory (C03) reflected the highest frequency of 37.04% within the theory variable, followed by the blended theory (C02) (27.78%), single theory (C01) (25.93%) while the complex theory (C04) reflected the least frequency (9.25%). This result indicates that blended theories are commonly used, but complex theories are least applied among the studies that investigated factors influencing student acceptance of MOOCs. Similarly, a very small sample (C05) reflected the highest frequency of 75.93% within the variable of the sample, followed by the small sample (C06) (14.81%), large sample (C07) (5.56%) while very large sample (C08) reflected the least frequency (3.70%). This result indicates that very small samples have been widely used, but very large samples are rarely used by researchers to explore factors influencing student acceptance of MOOCs. The factor of student satisfaction (C31) reflected the highest frequency of 14.81% within the factor variable, followed by student attitude (C26) (11.11%), behavioral intention (C09) (9.26%), perceived usefulness (C25) (9.26%), computer self-efficacy (C11) (7.41%), facilitating conditions (C15) (5.56%), intrinsic motivation (C18) (3.70%) while the other factors reflected the least frequency (1.85%). This result indicates that student satisfaction, student attitude, behavioral intention and perceived usefulness are widely used factors for exploring student acceptance of MOOCs.

 Table 4. Descriptive statistics of categories.

Label is the unique identifier for a category.

The mass of a variable category is the total of the Burt matrix of relative frequencies or probability. The very small sample category has the highest mass of 0.2531 to account for the 25.31% of the study data, while several factor categories have the lowest mass of 0.0062 to account for 0.62% of the study data. Previous studies that have used very small samples and extended theories are common, while those that recorded a low mass of 0.0062 are sporadic according to the study data.

Table 5 shows the contributions of the rotated coordinates based on the diagnostic indices of correlation (Corr) and contribution (Cont). Correlation represents the contributions of axes to points by squared correlations of points with the axes. The contribution represents the influence of points on the axes. The highest correlation values for the dimensions are 0.660, 0.482, 0.440, 0.234 and 0.318 respectively. This result means that dimension one accounts for most of the inertia of theory for complex theory and contributes to the inertia of sample for a very small sample, small sample, very large sample and factor for student habit and gamification perception. Dimension two accounts for most of the inertia of theory for self-regulation. Dimension three accounts for most of the inertia of theory and contributes to the inertia of the inertia of theory for self-regulation. Dimension three accounts for most of the inertia of theory and contributes to the inertia of the inertia of theory for self-regulation. Dimension three accounts for most of the inertia of theory and contributes to the inertia of theory for supple to the inertia of extended theory, sample for very small sample, large sample and factor for self-regulation. Dimension three accounts for most of the inertia of theory for blended theory and contributes to the inertia of extended theory, sample for y and provide theory is to the inertia of extended theory.

student habit. Dimension four accounts for most of the inertia of theory for blended theory and contributes to the inertia of single theory, sample for a very small sample, small sample, very large sample and factor for intrinsic motivation and student habit. Dimension five accounts for most of the inertia of sample for large sample and contributes to the inertia of theory for extended theory and factor for self-regulation. In terms of the contributions, the complex theory, large sample and blended theory contribute the most to the inertia of dimensions.

Table 5. Contributions of rotated coordinates.

Label is the unique identifier for a category, corr = correlation and cont = contribution.

Table 6 shows the inertia, quality and rotated principal coordinates of the study data. The inertia of a category is the proportion of the total inertia that the category contributes and quality is the dimensionality of the solution. The very small sample category was found to deviate from its expected value and contributed 0.70% to the total inertia. This result indicates that a very small sample is the most unusual under the basic assumption that none of the variables are correlated. The highest quality value of 0.885 was recorded for the single theory category, while the lowest quality value of 0.039 was recorded for the student

satisfaction category. This result indicates that single theory was best represented by the five dimensions, while student satisfaction has the poorest representation. The interpretation of the rotated principal coordinates has been suggested instead of the unrotated principal coordinates because they give straightforward explanations for dimensions greater than two [91,99]. The result of the rotated principal coordinates of variables with salient values in the asterisk mark is shown in Table 6. Salient coordinates are those with squared values larger than the mean [91,99].

Table 6. Rotated principal coordinates of variables with salient values.

Table value in asterisk (\*) indicates salient value and label is the unique identifier for a category.

Dimension one contrasts the factors identified from single theories to be perceived enjoyment, engagement on platform, intellectual capital, perceived functional value, social competence, social influence and teacher knowledge from the theories that identified intrinsic motivation and knowledge outcome as significant factors influencing student acceptance of MOOCs. Dimension two contrasts the factors identified from blended theories to be course quality, functional attachment, intrinsic motivation, perceived behavioral control, utility value, from the theories that identified facilitating conditions, flow experience, knowledge outcome, perceived ease of use, performance expectancy, perceived reputation, subjective norm and task technology fit as significant factors influencing student acceptance of MOOCs. Dimension three describes the factors identified using complex theories tested on a small sample to be knowledge outcome, social competence and gamification perception as significant factors influencing student acceptance of MOOCs. Dimension four describes the factors tested on a large sample to be intrinsic motivation and self-regulation as significant factors influencing student acceptance of MOOCs. Dimension five describes the factors identified using complex theories tested on a very large sample to be student habit as a significant factor influencing student acceptance of MOOCs. The five dimensions could be labeled respectively as single theory factors, blended theory factors, complex theory with small sample factors, large sample factors and complex theory with very large sample factors.

The focus of MCA is to provide an insight into a dataset through information visualization and it presents a useful application for visualizing associations amongst variable categories [92]. The first and second dimensions are usually plotted to examine the associations amongst variable categories [94]. The categories that are farther from the origin of the biplot are more discriminating, but the closer they are to the origin, the less distinct they are in general. That is unassociated variable categories are plotted far apart on the biplot and categories that are relatively closer from a combination cloud [93]. The present study has achieved a significant result about the discrimination measures obtained for the variables included in the MCA (Figure 2). It is highlighted as observed in the figure that the variable category of student habit becomes the most discriminating element of dimension one (x = -5.538; y = 0.704). Similarly, this can be said for the variable category of self-regulation (x = 1.294; y = 5.134) with regards to dimension two. The points farther away from the plot origin are more influential and those at the opposite sides of the plot indicate that a component contrasts these variable categories. The variable categories of student habit and self-regulation are more influential while dimension two highly contrasts the variable category of student habit from the category of self-regulation.

Figure 2. Discrimination measures of the variables.

The biplot correspondence graph for the different contemplated variable categories of dimensions 1 and 2 accounts for approximately 51.60% of the explained inertia (Figure 3). The categories of different variables are associated when they are closed to each other, but

Dimension 1 (31.6% Adi)

categories of the same variable that are closed to each other are said to be similar. The biplot constructs the coordinates of the variable categories to visually observe the associations in data and interpret the principal components of the categories [92]. This result generally indicates the existence of associations through closeness and similarities by a combination cloud of variable categories. The biplot of the points that form the three variables of this study permits an organized structure to be drawn around four main levels of associations. The first is composed of single theories. It is associated with factors of social competence and a combination cloud of factors of teacher knowledge, social influence, perceived functional value, intellectual capital, engagement on platform and perceived enjoyment. The second is fulfilled by blended theories. It is more associated with factors of computer self-efficacy, gamification perception, intrinsic motivation and a combination cloud of factors of utility value, perceived behavioral control, functional attachment and course quality. The third is formed by extended theories. It is associated with factors of facilitating conditions, self-regulation, knowledge outcome and a combination cloud of factors of task technology fit, subjective norm, perceived reputation, performance expectancy, perceived ease of use and flow experience. It can be observed that student sample, that is very small sample, small sample, large sample, or very large sample does not play a discriminating role in these three associations. The last is formed by complex theories. It is more associated with very small sample, small sample, large sample, very large sample, factors of perceived usefulness, student attitude and a combination cloud of factors of student satisfaction, student habit and behavioral intention.

Figure 3. Biplot of the first and second dimensions.

# 4. Discussions

The overarching objective of this study was to use the data science method of MCA to explore hidden associations among factors influencing student acceptance of MOOCs and heterogeneity sources. This has led to the development of an appropriate dataset based on a comprehensive review of related studies. The dataset was processed using the MultipleCar toolbox [91] and MCORRAN2 Matlab code [95], which are general software suitable for implementing correspondence analysis. The theory, sample and factor are the core variables of the dataset that were considered for the MCA to detect hidden associations. The number of observations in a study often refers to as sample size is an important research consideration. Sample size influences the precision, robustness and validity of the findings from research. The larger the sample size, the more robust is likely to be the study result, but it should not be either too small or too large. On one hand, very small samples can undermine the validity and prevent the generalization of findings. On the other hand, very large samples tend to amplify small differences into statistically significant differences and emphasize insignificant statistical differences [24]. Theoretical models in research offer the footing to establish credibility and application of a wrong theory can lead to erroneous interpretations, judgments and weedy conclusions. However, the selection of the right theory for research can enhance robustness, relevance and impactful findings [25].

This study has used MCA for the first time to investigate hidden associations among the variables of theory, sample and factor. The MCA enables the exploration of hidden associations among variable categories and observations not observed in the literature. It has helped in this study, to detect useful insights about hidden associations among the factors influencing student acceptance of MOOCs, theoretical models applied in the previous studies for factor exploration and sample sizes of students who participated in the different studies. The work reported in this paper is an important assignment that has been overlooked in the literature as evidence from the comprehensive review of the existing studies. Previous studies have improved the understanding of the application of MCA for factor exploration. Meta-regression analysis was used to show that "theoretical model" and "sample size" were statistically significant sources of heterogeneity in factors influencing student acceptance of MOOCs [23]. However, the investigation of associations among influencing factors and sources of heterogeneity that could have yielded significant insights was not previously found.

The MCA has helped this study address the literature chasm and further enrich the existing studies on MOOCs in the niche area of technology acceptance. There are some important findings from this study as elucidated as follows. Complex theories that combine two or more supplementary factors are rarely applied, but blended theories are commonly used for exploring factors influencing student acceptance of MOOCs. This study has found five previous studies in the literature that have used complex theories for exploring significant factors influencing student acceptance of MOOCs [21,53,81,82,84]. Very small samples usually between 101 and 411 are widely used, but very large samples are rarely used for exploring factors influencing student acceptance of MOOCs. The studies that have used very small samples constitute about 75.93% and the examples of such studies with less than 200 samples include [15,16,19,71,79,84]. Student satisfaction [7,19, 52,53,60,74,75,82], student attitude [10,11,57,68,79,83], behavioral intention [5,21,51,59,72] and perceived usefulness [1,2,13,61,70] are the widely used factors for exploring student acceptance of MOOCs. The student satisfaction factor was shown in meta-analysis research to be the main significant factor influencing student acceptance of MOOCs [23]. A very small sample of students is the most unusual under the basic assumption that none of the variables are correlated. The single theory was best represented by the five dimensions, whilst student satisfaction has the poorest representation. The five dimensions found for dimension reduction were easily interpreted and labeled as single theory factors, blended theory factors, complex theory with small sample factors, large sample factors and complex theory with very large sample factors. The salient coordinates in the first and second dimensions suggest that these two dimensions are bipolar and the other three are unipolar. The bipolar dimensions contrast the influencing factors that are on the opposite sides of the dimensions [91]. The simplified principal coordinates of variables and observations were obtained using the widely known varimax rotation algorithm as recommended by the previous authors [91,99].

The results of this study generally conclude the existence of four main levels of associations. The first is formed by factors identified by single theories. It is associated with social competence and a combination cloud of factors of teacher knowledge, social influence, perceived functional value, intellectual capital, engagement on platform and perceived enjoyment. The second describes the factors identified by blended theories. It is more associated with computer self-efficacy, gamification perception, intrinsic motivation and a combination cloud of factors of utility value, perceived behavioral control, functional attachment and course quality. The third is composed of factors identified by extended theories. It is associated with facilitating conditions, self-regulation, knowledge outcome and a combination cloud of factors of task technology fit, subjective norm, perceived reputation, performance expectancy, perceived ease of use and flow experience. The last is formed by factors identified by complex theories. It is associated with very small sample, small sample, large sample, very large sample, factors of perceived usefulness, student attitude and a combination cloud of factors of student satisfaction, student habit and behavioral intention that explain student behaviors toward MOOC acceptance.

#### 5. Conclusions

Different studies on the applications of MCA have been conducted in multitudinous fields over the past few decades. However, no one has focused on its unique application for exploring factors influencing student acceptance of MOOCs, which is the overarching objective of the research reported in this paper. It is pragmatic to explore hidden associations in a database of influencing factors to increase the understanding of multifarious heterogeneously conflicting factors of MOOC acceptance. The understanding of student acceptance of MOOCs will lead to better prediction of the use of the innovative education model and its associated information resources. In addition, it can lead to increased personal control of knowledge and better productivity of the education system.

The one discernible limitation of the present study is that reviewed articles were limited to 54 studies because of the criteria used to initiate the literature search. The search parameters might have excluded a significant number of studies that could have enriched the study findings. This intrinsic limitation could be addressed in future research by using other methodological techniques with less limiting article selection criteria to accommodate for expansion of information and generate more suitable data for analysis. Second, this study has focused mainly on student acceptance of MOOCs but extending the study to capture the perceptions of teachers could have yielded more perceptive findings. Future studies may examine the acceptance of MOOCs by teachers for a more comprehensive understanding of their usage. Moreover, future research can compare the acceptance of MOOCs by students with acceptance by teachers to discover more useful insights. This kind of research would be able to depict whether hidden associations exist in the perceptions of students and teachers on their acceptance of MOOCs. Nonetheless, this correspondence analysis study has provided valuable information regarding hidden associations amongst the factors influencing student acceptance of MOOCs.

More specifically, this study has found some important outcomes through the unique application of MCA. These outcomes include the following. A very small sample is the most unusual under the basic assumption that none of the variables are correlated. The simplified principal coordinates of variables and observations were obtained using the widely known varimax rotation algorithm. Five principal dimensions were found in this study that explained 81.800% of the total inertia based on the adjusted inertia. A single theory was best represented by the five dimensions, while student satisfaction has the poorest representation. The variable categories of student habit and self-regulation are more influential while dimension two highly contrasts the variable category of student

habit from the category of self-regulation. The study has found the existence of four main levels of associations composed of single, blended, extended and complex theories respectively. Each level is associated with distinct variable categories and a combination cloud of similar variable categories.

Future work will investigate the behavior and performance of the cluster analytical strategy on the same data of this study for further insights that are not exposed by the factor analytical strategy.
