

## Supplementary

The input data of the above three models includes leaf area index (LAI), net radiation (Rn), air temperature (Ta), precipitation (P), air pressure (Pa), relative humidity (RH), and land cover (LC) (Supplementary Table S1). To investigate the influences of vegetation and meteorological variables on ET estimations, three sets of LAI data and two sets of meteorological data were used in this study. A total of 18 ensembles evapotranspiration (ET) products are obtained from the three ET models with different combinations of inputs data (Supplementary Table S2).

**Supplementary Table S1.** Variables used as input to derive evapotranspiration (ET) in three models.

\* '√' represents the forcing data used in the model.

Models	Leaf Area	Meteorological variables					Land Cover
	Index	Ta	P	Pa	RH	Rn

---

In addition, we analyze the statistical description (i.e., mean, maximum, minimum, standard deviation, skewness coefficient, and kurtosis coefficient) of the data used for the study should be provided. The statistical parameters of the observed ET data at sites were presented in Supplementary Table S3, which provided a summary of the annual mean, maximum, minimum, standard deviation (SD), skewness, and kurtosis values of ET for 43 sites. The SD values varied from 6.22 to 48.90 mm/month. The skewness values ranged from -0.11 to 1.22, within the conventional acceptable limit of  $\pm 2$ , indicating that the data were normally distributed. The kurtosis values at most sites were lower than 3. The main information and statistical parameters of the observed ET data across 32 catchments were given in Supplementary Table S4. The SD values varied from 6.65 mm/month to 36.55 mm/month. The skewness values at most catchments were within the acceptable limit of  $\pm 2$ , and the kurtosis values of most catchments were lower than 3.

**Supplementary Table S3.** The monthly statistical parameters of the measured ET data at flux sites.
