Abstract: Background: Nutrition plays a key role in modulating the likelihood of healthy ageing. In the present study, we aimed to conduct a systematic review to assess the impact of nutrition on healthy ageing in Asia. Methods: The systematic review was registered in the International Prospective Register of Systematic Reviews database (CRD42023408936) and conducted based on the Preferred Reporting Items for Systematic Reviews and Meta-Analyses guidelines. The PubMed, Web of Science, and Embase databases were searched up to February 2023 without language restrictions. We included prospective cohort studies that evaluated the associations of intake of a single food or consumption of a single nutrient at midlife; adherence to various dietary patterns at midlife; and improved adherence to dietary patterns from mid- to late life with the likelihood of healthy ageing and its components. Results: Out of 16,373 records, we included 71 papers comprising 24 cohorts from Singapore, China, Japan, and Thailand. The healthy ageing components included cognitive function, physical function, and depression. The majority of studies supported the observation that the likelihood of healthy ageing and its components in late life was positively increased by a higher consumption of healthy foods, such as vegetables, fruits, fish, nuts, legumes, tea, milk, and dairy, at midlife, and also by greater adherence to dietary patterns with high diversity scores or high total antioxidant capacities. Furthermore, improved adherence to healthy dietary patterns from mid- to late life also increased the likelihood of healthy ageing in late life. Conclusion: Consuming healthy foods and adhering to healthy dietary patterns at midlife can promote the likelihood of healthy ageing. Moreover, improving diet quality from mid- to late life can still be beneficial.

Keywords: nutrition; diet; healthy ageing; Asia; cohort

1. Introduction

An increase in life expectancy and a decline in fertility rates have resulted in accelerated ageing of the population in many countries, including those in Asia. By 2050, a quarter of Asia's population is predicted to be ≥ 60 years old, which will inevitably lead to an increased number of older adults with chronic diseases and disability, and with profound consequences for health, health systems, the workforce, and budgeting for many Asian countries [1]. To provide a public health framework for action, World Health Organization has released the "World report on ageing and health", which calls for comprehensive public health action to promote healthy ageing, the latter being defined as developing and maintaining the functional ability that enables well-being in older age [2].

Nutrition and diet have been established as possessing some of the most important influences on health and ageing, with the overwhelming majority of evidence coming

from Western populations [3,4]. However, there is still limited evidence on the associations between diet and nutrition at midlife and the likelihood of a multidimensional concept of healthy ageing and its components in late life in Asian populations.

In the present review, we aimed to conduct a comprehensive overview of Asian studies on the prospective associations of consumption of a single food or nutrient at midlife; adherence to various dietary patterns at midlife; and improved adherence to dietary patterns from mid- to late life with the likelihood of healthy ageing and its components. The results of this review could provide important evidence to develop better region-specific strategies aimed at promoting healthy ageing in Asia.

2. Methods

This systematic review was registered in the International Prospective Register of Systematic Reviews database (CRD42023408936). We followed the Preferred Reporting Items for Systematic Reviews and Meta-Analyses statement. The first two authors (Y.F.Z. and X.Y.S.) independently performed the study selection, data extraction, and assessment of study quality, and divergences were solved by discussion or consulting a third author (K.W.P.).

2.1. Data Sources and Searches

PubMed, EMBASE, and Web of Science were searched for studies investigating the relationship between nutrition and healthy ageing from the database's inception to February 2023. Table S1 shows the strategies used for each database. In brief, the search terms included the Medical Subject Heading terms and related exploded versions, as well as keywords in titles or abstracts related to the following themes: 'diet', 'nutrition', 'food', 'dietary pattern', 'healthy aging', 'dementia', 'cognitive', 'depression', 'activities of daily living', 'physical function', 'self-perceived health', 'function-limiting', 'major chronic diseases', 'cohort', 'prospective', 'follow up', and 'longitudinal'. No language restriction was applied. In addition, reference lists of the included studies and relevant reviews were searched to identify further publications. We included cohort studies conducted in countries of Asia (defined as Eastern Asia, Southern Asia, and Southeastern Asia) and outcome measures assessed in older adults (aged ≥ 60 years). Although the global cut-off for older persons is ≥ 65 years, we included those aged 60–65 years as well, in order to account for a different definition of 'older adults' in some Asian countries [5].

2.2. Study Selection

The following types of studies were excluded: (1) duplicate publications or those reporting from the same cohort (the one with smaller sample size or shorter follow-up duration would be excluded); (2) unrelated to nutrition or healthy ageing; (3) not a prospective design; (4) not from a peer-reviewed publication; (5) ageing outcomes measured in those below aged <60 years; (6) and not conducted in Asia.

2.3. Data Extraction and Quality Assessment

Predesigned tables were used to extract information, including cohort name, country, sample size, age, median/mean follow-up duration, definition and acquisition of exposure, and assessment of outcome. The Newcastle–Ottawa Scale was used to assess the quality of the studies. A study was considered high quality if it received ≥ 6 points out of 9 points [6].

3. Results

3.1. Study Selection and Characteristics

We identified 16,373 studies in the literature search. Among these, 3875 duplicates were excluded. After screening the titles and abstracts, 12,129 citations were excluded, and the remaining 369 studies were included for full-text assessment. We further excluded 298 articles after full-text reading (reasons are shown in Figure 1) and included 71 studies comprising 24 cohorts in this review (Figure 1).

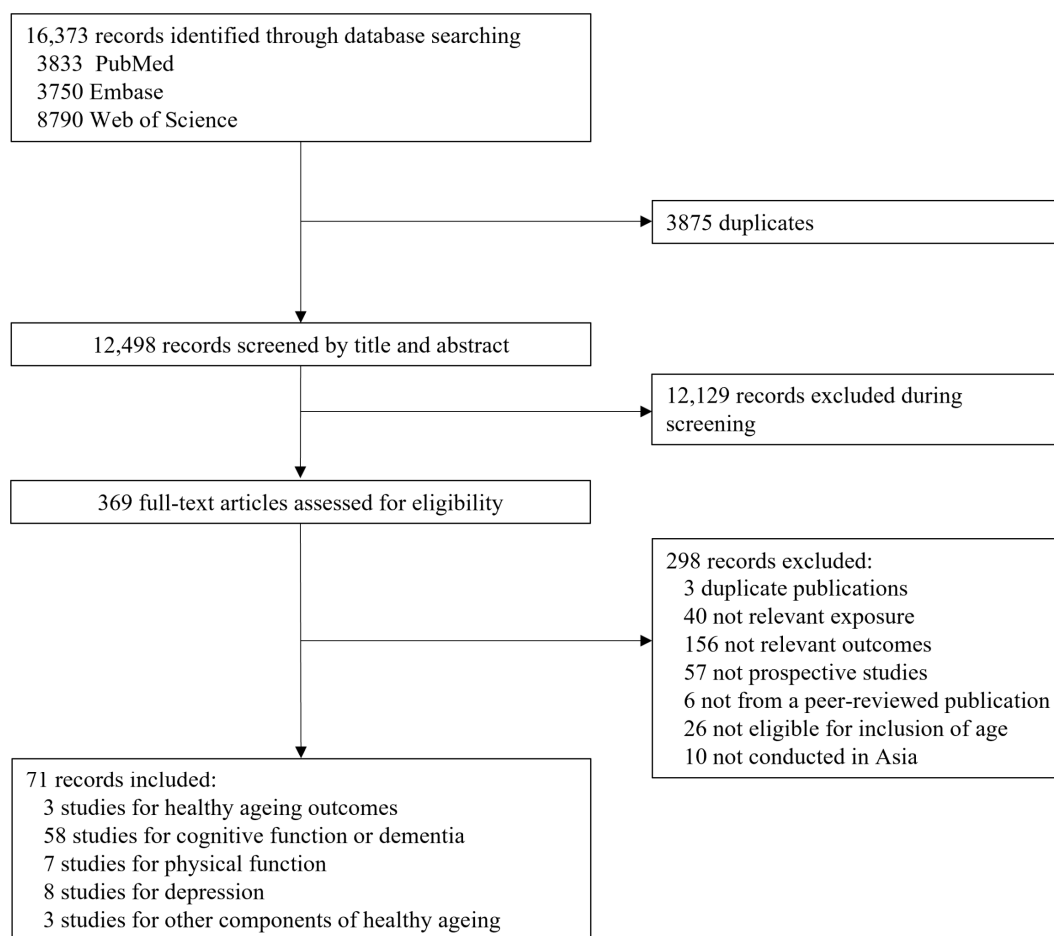

Figure 1. Flow chart of the study selection.

The quality of the included studies, as assessed using the Newcastle–Ottawa Scale, was considered to be high for all 71 studies (Table S2). The characteristics of the eligible studies are shown in Table 1. Sixteen cohorts were from China, five from Japan, two from Singapore, and one from Thailand. Most of the studies were conducted among middle-aged or older participants, ranging in age from 40 to 89.2 years. The sample size ranged between 427 and 41,447, and the follow-up period ranged between 1.4 and 25.0 years. Food frequency questionnaires (FFQs) were used for data collection in most cohorts, except for the China Health and Nutrition Survey (CHNS), the Singapore Longitudinal Aging Studies, the National Institute for Longevity Sciences—Longitudinal Study of Aging (NILS-LSA), and the Zhejiang Ageing and Health Cohort Study. In these studies, 24 h dietary recalls for 3 consecutive days [7], 3-day dietary records [8–10], or simple food consumption questions [11–13] were used.

Table 1. Characteristics of studies included in the systematic review.

Author, Year (Ref)	Cohort	Country	Participants, n	Age, y *	Follow-Up, y *	Nutrition	Nutrition Measures	Ageing Outcomes	Outcome Definition or Measures
Zhang et al., 2021 [7]	The CHNS	China	3085	>60	4–6	Dietary diversity score	24 h dietary recalls for 3 consecutive days	Healthy ageing, physical and cognitive function	Healthy ageing included physiological, psychological, and sociological aspects.
Zhou et al., 2020 [14]	The Singapore Chinese Health Study (SCHS)	Singapore	14,159	53.3 (6.1)	20	Diet quality, scored by the aMED, DASH diet, AHEI-2010, PDI, and hPDI.	165 items, semi-quantitative FFQ	Healthy ageing, depression, physical function	Healthy ageing included: major chronic diseases, cognitive function, IADL, depression, self-perceived health, physical functioning, and function-limiting pain.
Zhou et al., 2022 [15]	The SCHS	Singapore	12,316	53.1	20	Changes in DASH scores	165 items, semi-quantitative FFQ	Healthy ageing, depression, physical function	Healthy ageing included: major chronic diseases, cognitive function, IADL, depression, self-perceived health, physical functioning, and function-limiting pain.
Aihemaitijiang et al., 2022 [16]	The Chinese Longitudinal Healthy Longevity Survey (CLHLS)	China	2282	≥60	7	Dietary diversity score	A non-quantitative frequency questionnaire of 13 food groups	Physical function	Physical function was judged according to the 8-item IADL.
Hata et al., 2022 [17]	The Ota Genki Senior Project	Japan	10,318	≥65	5.1	Dietary variety score	A 10-item FFQ	Physical function	Functional disability was defined by the LTCI certification.
Zhang et al., 2020 [18]	The CHNS	China	5004	58.6	9	Dietary diversity score	24 h dietary recalls for 3 consecutive days	Physical function	ADL disability was defined as having any difficulty in at least one of the five self-care tasks.
Matsuyama et al. 2019 [19]	The Ohsaki Cohort 2006 Study	Japan	2923	≥65	10	The Japanese Diet Index	A 39-item FFQ	Physical function	Functional disability was defined using the LTCI certification.
Tomata et al., 2012 [20]	The Ohsaki Cohort 2006 Study	Japan	13,988	≥65	3	Green tea	A 39-item FFQ	Physical function	Functional disability was defined using the LTCI certification.
Chan et al., 2014 [21]	The Mr. and Ms. Os cohort	China, Hong Kong	4000	≥65	3.9	Dietary patterns related to vegetables, fruits, snacks, drinks, milk products, and meat/fish	A 280-item FFQ	Depression	Depression was assessed using the GDS.
Pei et al., 2022 [22]	The CLHLS	China	2873	80.3	4	Dietary patterns	A non-quantitative frequency questionnaire of 13 food groups	Depression	Depression was assessed using the PhenX Toolkit

Table 1. Cont.

Author, Year (Ref)	Cohort	Country	Participants, n	Age, y *	Follow-Up, y *	Nutrition	Nutrition Measures	Ageing Outcomes	Outcome Definition or Measures
Matsuoka et al., 2017 [23]	The Japan Public Health Center-based Prospective (JPHC) Study	Japan	1181	40–69	Up to 25	Fish intake and PUFA	A 147-item FFQ	Depression	Depression was assessed using the CES-D.
Tsai et al., 2011 [24]	The Survey of Health and Living Status of the Elderly in Taiwan	China	1069	≥65	4	Vegetables and fruits	An FFQ covering 7 food categories	Depression	Depression was assessed using the CES-D.
Fann et al., 2022 [25]	The Taiwan Longitudinal Survey on Aging (TLSA)	China	4400	≥53	16	Vegetables and fruits	An FFQ covering 9 food categories	Depression	Depression was assessed using the CES-D.
Zhang et al., 2022 [13]	The Zhejiang Ageing and Health Cohort Study	China	6253	68.2	6	Soy products	Single question	Depression	Depression was assessed using the PHQ-9.
Zhang et al., 2020 [26]	The CHNS	China	4356	61.9 (7.9)	4	Dietary diversity score	24 h dietary recalls for 3 consecutive days	Cognitive function	Cognitive function was assessed using the TICS-m.
Qin et al., 2015 [27]	The CHNS	China	1650	≥55	5.3	Dietary pattern, aMED	24 h dietary recalls for 3 consecutive days	Cognitive function	Cognitive function was assessed using the TICS-m.
Shang et al., 2021 [28]	The CHNS	China	2307	63.3 (7.0)	7 (2–11)	Five dietary patterns	24 h dietary recalls for 3 consecutive days	Cognitive function	Cognitive function was assessed using the TICS-m.
Xu et al., 2018 [29]	The CHNS	China	4874	64 (59, 71)	-	Dietary patterns: traditional Chinese, protein-rich, starch-rich	24 h dietary recalls for 3 consecutive days	Cognitive function	Cognitive function was assessed using the TICS-m.
Zhang et al., 2023 [30]	The CHNS	China	6308	≥55	Up to 21	A vegetable-pork dietary pattern	24 h dietary recalls for 3 consecutive days	Cognitive function	Cognitive function was assessed using the TICS-m.
Li et al., 2019 [31]	The CHNS	China	4822	≥55	15	Nut intake	24 h dietary recalls for 3 consecutive days	Cognitive function	Cognitive function was assessed using the TICS-m.
Qin et al., 2014 [32]	The CHNS	China	1566	63 (6)	5.3	Fish intake	24 h dietary recalls for 3 consecutive days	Cognitive function	Cognitive function was assessed using the TICS-m.

3.2. Association between Nutrition and Healthy Ageing

Three studies [7,14,15], which included 17,244 participants in two cohorts, investigated the multidimensional concept of healthy ageing. In the SCHS, healthy ageing was defined as the absence of specific chronic diseases; good mental and overall self-perceived health; good physical functioning; and a lack of adverse outcomes of cognitive impairment, limitations in instrumental activities of daily living (IADL), or function-limiting pain [14,15]. Data from the SCHS reported that a greater adherence to various healthy dietary patterns at midlife, defined by the alternate Mediterranean diet (aMED), the Dietary Approaches to Stop Hypertension (DASH) diet, the Alternative Healthy Eating Index (AHEI)-2010, the overall plant-based diet index (PDI), and the healthful plant-based diet index (hPDI), was associated with a higher likelihood of healthy ageing in late life, with the odds ratio (OR) comparing the highest with the lowest quartile of diet quality scores ranging from 34% to 53% for healthy ageing [14]. Furthermore, consistent or improved adherence to the DASH diet from mid- to late life was associated with a 19% to 108% higher likelihood of healthy ageing [15]. In the CHNS, a healthy ageing score was calculated by adding up the standardized scores for physical functional limitation, comorbidity, cognitive function, and psychological stress, with a lower score indicating a healthier ageing process [7]. Data from the CHNS revealed that a higher level of dietary diversity was associated with a lower score, representing healthier ageing (T3 vs. T1: β , -0.16 ; 95% confidence interval [CI], -0.20 to -0.11) [7]. A summary of the associations between diet/nutrition and the outcomes of ageing is presented in Figure 2.

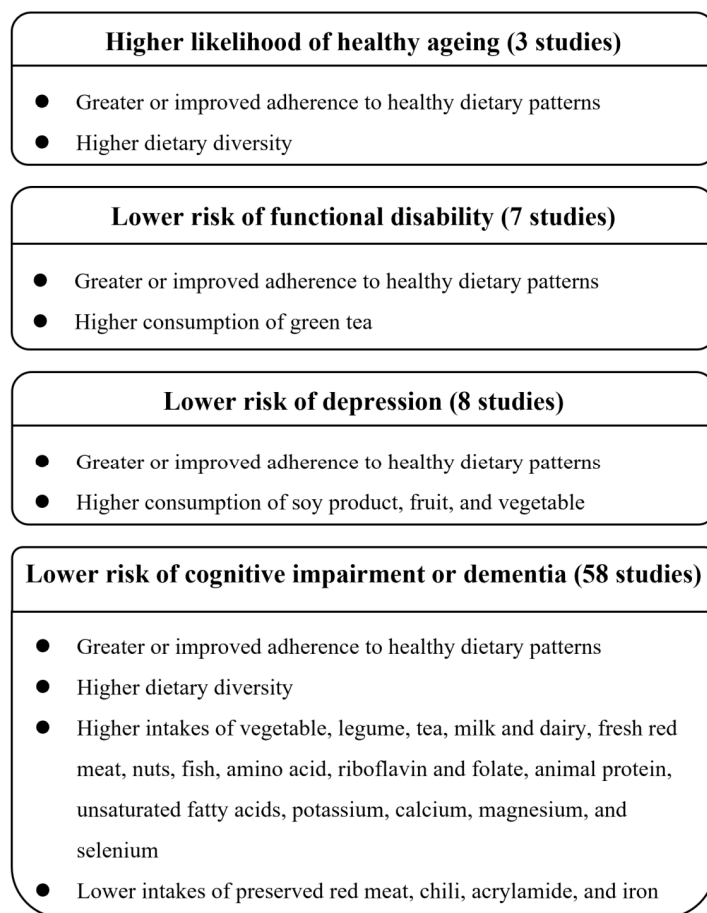

Figure 2. Summary of major findings regarding the associations between diet/nutrition and outcomes of ageing.

3.3. Association between Nutrition and Physical Function

Seven studies [14–20], which included 48,674 participants, studied physical function components and how they are affected by ageing. Among these, physical function was assessed using the eight-item IADL scale [14–16], the Long-Term Care Insurance (LTCI) certification [17,19,20], or by the self-reported ability to conduct five self-care tasks (standing up after sitting for a long time, dressing, toileting, bathing, and feeding) [18]. Inconsistent findings were found regarding the association between the dietary diversity score and IADL limitation or incident disability, with one study showing a higher average dietary diversity score to be associated with a decreased risk of ADL disability (T3 vs. T1: hazard ratio, 0.50; 95% CI, 0.39–0.66) [18], while other studies reported null associations [16,17]. Regarding dietary patterns, greater adherence to various healthy dietary patterns [14,16,19], such as aMED, DASH, AHEI-2010, PDI, hPDI diet, fruit–egg–milk pattern, vegetable–meat–fish pattern, condiment and tea pattern, and the improved Japanese Diet Index, as well as increased adherence to the DASH diet [15], was significantly associated with a lower risk of IADL limitation or functional disability. For individual nutrients, data from the Ohsaki Cohort 2006 study showed that a higher consumption of green tea was significantly associated with a lower risk of incidents of functional disability, with a hazard ratio (95% CI) of 0.90 (0.77–1.06) among respondents who consumed 1–2 cups green tea/d; 0.75 (0.64–0.88) for those who consumed 3–4 cups/d; and 0.67 (0.57–0.79) for those who consumed ≥ 5 cups/d in comparison with those who consumed < 1 cup/d (p -trend < 0.001) [20].

3.4. Association between Nutrition and Depression

Eight studies [13–15,21–25], which included 33,935 participants, investigated the components of depression in ageing. Among these, depression was assessed using the Center for Epidemiological Scale—Depression (CES-D) score [23–25], the Geriatric Depression Scale (GDS) [14,15,21], the Patient Health Questionnaire-9 (PHQ-9) [13], or the PhenX Toolkit [22]. As for dietary patterns, greater adherence to established healthy dietary patterns, such as the aMED, DASH, AHEI-2010, PDI, and hPDI diets [14], as well as an improvement in diet quality measured by these patterns [15], was associated with a lower risk of depression. However, for dietary patterns identified through a posteriori analytic methodology, while there were no significant associations of ‘vegetables-fruits’, ‘snacks-drinks-milk products’ and ‘meat-fish’ dietary patterns with a subsequent report of depressive symptoms among Chinese in Hong Kong [21], the vegetable–egg–beans–milk dietary pattern was associated with a lower risk of depression (OR, 0.65; 95% CI, 0.49–0.87), and the salt-preserved vegetable–garlic dietary pattern was associated with a higher risk of depression (OR, 1.33; 95% CI, 1.00–1.77) according to a study from the CLHLS [22]. For individual foods, higher intakes of soy products, fruits, and vegetables were associated with a lower risk of depression [13,24,25], whereas other food categories, including eggs, meat/poultry, seafood, dairy, legumes, grains, and tea, showed no significant associations [24]. Inconsistent results were shown for fish intake, with some studies reporting an inverse association [23] and others reporting null association [24].

3.5. Association between Nutrition and Cognitive Function or Dementia

Fifty-eight studies, which included 488,056 participants, investigated cognitive function components of ageing. Among these, cognitive function was assessed using the Telephone Interview for Cognitive Status—modified (TICS-m) [7,26–37], the Mini-Mental State Examination (MMSE) [8,9,11,12,38–52,59,61,65,73,77], the Montreal Cognitive Assessment (MoCA) [64,68,74,75], the Short Portable Mental Status Questionnaire (SPMSQ) [69,70], or the World Health Organization/University of California-Los Angeles Auditory Verbal Learning Test (AVLT) [71], or was evaluated by asking questions about walking capability, hearing/vision, memory, and decision-making ability [72]. Diagnoses of dementia were made in accordance with the Diagnostic and Statistical Manual of Mental Disorders [53–56,60,76]; the criteria of the LTCI certification [10,57,58,62,63]; or the Interna-

tional Statistical Classification of Diseases and Related Health Problems, Tenth Revision (ICD-10) [67]; or were obtained from the National Health Insurance Database [66].

For dietary diversity, a higher score was associated with a lower risk of cognitive impairment [7,38], bad memory [26], and disabling dementia [57]. Regarding dietary patterns, greater adherence to healthy dietary patterns, such as the aMED, DASH, AHEI-2010, modified AHEI, PDI, hPDI diet [39,40,43,64,71], Chinese Food Pagoda [72], “vegetable” [68] or “vegetable-pork” dietary pattern [30], “protein-rich” dietary pattern [29], beans and mushroom dietary pattern [28], Japanese dietary pattern [10,53,63], or wheat-based diverse diet [27], as well as improvements in diet quality [44], were associated with a lower risk of cognitive impairment, cognitive/memory decline, and incident dementia. However, the Western dietary pattern [69], animal-based dietary pattern [41], unhealthful PDI [39], and starch-rich dietary pattern [29] increased the risk of cognitive decline.

For individual foods, higher intakes of vegetables and their constituent nutrients [50,54,64,65,67,70], legumes [42], tea [8,34,66], milk and dairy [48,55], fresh red meat [47,74], nuts [31,51], and fish [32,60,62,66] were associated with a lower risk of cognitive impairment, cognitive decline, and dementia. For individual nutrients, a higher dietary total antioxidant capacity [45] and higher intakes of amino acids [61], riboflavin and folate [49,75], animal protein [33], unsaturated fatty acids, polyunsaturated fatty acids (PUFAs), and n-3 PUFA supplements [11,52,60,75] were associated with a lower risk of cognitive impairment, cognitive decline, and dementia. In contrast, higher consumption of preserved red meat [47], chili [35], acrylamide [73], and protein intake from grains [33] were associated with a higher risk of cognitive impairment. No significant associations were found for thiamine, niacin, vitamin B-6 [49], sugar-sweetened beverages [46], or coffee [8]. Inconsistent findings were found for intakes of fruit, soy, and isoflavones, as well as vitamin B-12, with different studies showing either inverse associations [9,50,67,70], positive associations [59], or a U-shaped relation [77], and others reporting null associations [48,49,54,58,65].

For dietary minerals, higher intakes of potassium, calcium, magnesium, and selenium were associated with a lower risk of dementia [54,56,76] or a reduced likelihood of reporting memory decline [37], whereas a higher iron intake was associated with poorer cognitive function [36].

3.6. Association between Nutrition and Other Components of Healthy Ageing

For other components of healthy ageing, greater adherence to various healthy dietary patterns at midlife, as well as consistent or improved adherence to the DASH diet from mid- to late life, was associated with a higher likelihood of having good self-perceived health and physical functioning and a lower likelihood of having chronic diseases and function-limiting pain [14,15]. In addition, a higher dietary diversity score was associated with less psychological stress (T3 vs. T1: OR, 0.59; 95% CI, 0.49–0.72); however, the association between the dietary diversity score and the number of comorbidities was insignificant [7].

4. Discussion

In this systematic review, we used data from population-based longitudinal cohort studies to investigate the prospective associations between nutrition at midlife and the likelihood of healthy ageing and its components in late life in Asia. Most of the current evidence has supported the positive associations of higher intakes of healthy foods at midlife, such as vegetables, fruits, fish, nuts, legumes, tea, milk, and dairy. Furthermore, a higher dietary diversity or total dietary antioxidant capacity at midlife, as well as greater or improved adherence to healthy dietary patterns from mid- to late life, was also associated with the likelihood of healthy ageing and its components in late life.

The currently available literature supports that adherence to various healthy dietary patterns is associated with a higher likelihood of healthy ageing. These healthy dietary patterns, either determined a priori or identified through a posteriori analytic methodology, are similar in that they recommend high consumption of fruits, vegetables, and

whole grains; moderate consumption of dairy products, fish, and poultry; and low consumption of sugary beverages, saturated fat, added sodium, red meat, and processed food [14,16,19,39,40,43,54,64,71]. However, these results should be interpreted with caution, given that differences exist in the major ingredients and culinary methods used between Asian and Western cuisines. For example, the Mediterranean diet emphasizes fruits, vegetables, whole grains, and olive oil as staples, while Asian diets commonly rely on white rice, noodles, and other grains as primary sources of energy [72]. This variation in staple foods may significantly impact nutrient composition and overall dietary patterns.

In addition, the findings confirmed that maintaining consistently high DASH scores was related to a greater likelihood of healthy ageing than keeping consistently low DASH scores [15]. Moreover, those who managed to improve their DASH scores by >10% from mid- to late life were able to increase their likelihood of healthy ageing [15]. Hence, our findings provide evidence for the recommendation of the 2020–2025 Dietary Guidelines Advisory Committee that “it is never too late to eat healthfully” [78]. More studies are warranted to explore strategies in order to achieve a sustained change in dietary behaviours in the real world and to create an environment in which to make healthy eating affordable and accessible.

Dietary diversity is an important index reflecting nutrient adequacy. Increasing dietary diversity can ensure sufficient nutrient intake and improve dietary quality to promote healthy ageing [7,38]. However, mixed findings were observed regarding the association between dietary diversity score and IADL limitation or incident disability. Data from the CLHLS, including 2285 subjects aged >60 years with a maximum follow-up of 7 years, reported that dietary diversity had no effect on the occurrence of IADL limitation [16]. The Ota Genki Senior Project, including 10,318 Japanese adults aged >65 years with a median follow-up of 5.1 years, found that dietary variety was not independently associated with incident disability [17]. However, data from 5004 participants in a study of the CHNS reported that higher dietary diversity scores were associated with fewer physical functional limitations [18]. There are several potential reasons for these mixed findings. First, there is substantial variability in the measures of physical function and functional disability due to the use of different scales and instruments in different studies. Second, the intake frequency and scoring criteria of dietary diversity scores varied substantially across studies. For example, the dietary diversity score was calculated according to the intake frequency of 13 food groups, and the low group was defined as <7 in the CLHLS [16], whereas it was calculated according to the intake frequency of 10 food groups and a low group was defined as <3 in the Ota Genki Senior Project [17]. Nevertheless, our review concurs with the World Health Organization [79] and Chinese dietary guidelines [80] in terms of recommending adherence to a diverse diet to achieve healthy ageing in later life.

The associations between the intakes of fruits and fish and the likelihood of healthy aging components were inconsistent, and this could be explained by differences in the ranges of consumption among different populations. For example, the Hisayama study, which included 1071 Japanese participants, observed small differences among quintiles of fruit intake, with the range of the highest quartile of fruit intake being ≥ 115 g/d for men (≥ 100 g/d for women) and the lowest quartile being ≤ 32 g/d for men (≤ 21 g/d for women) [54]. However, there were substantial differences among the quartiles of fruit intake in the SCHS, with the median fruit intake in the highest and lowest quartile being 383.44 g/d and 76.30 g/d, respectively [50]. Notably, the SCHS applied a 165-item FFQ which included 14 fruits [50], whereas the Hisayama study applied a 70-item FFQ, and might have underestimated the fruit intake in this population [54]. Differences in methods of categorizing the intake of fish across studies could also explain these inconsistent results. For example, fish intake was divided into <3 times/week and ≥ 3 times/week in the Survey of Health and Living Status of the Elderly, and a null effect was reported for fish intake and risk of depression [24]. In contrast, fish intake was divided according to quartile consumption in the JPHC study, and a reduced risk of major depressive disorder was found in the third quartile (111.1 g/d) [23].

To the best of our knowledge, this is the first study which has systematically reviewed the association between nutrition in midlife and the likelihood of healthy ageing in late life according to Asian cohort studies. In addition, the quality of the included studies was considered to be high. Several limitations should be considered. First, except for the analyses of the association between nutrition and cognitive function, analyses related to healthy ageing, physical function, depression, and other components of healthy ageing only included limited studies. In addition, although we included 71 studies from 24 cohorts, these cohorts were situated in China, Japan, Singapore and Thailand, and represented a small proportion of the diverse Asian population. Second, substantial variations existed across the studies in terms of the measures of exposure, definitions of outcomes, sample sizes, and follow-up durations. Nonetheless, the overall results are consistent in that they recommend the consumption of healthy foods and adherence to healthy dietary patterns at midlife for healthy ageing. Moreover, improving the quality of one's diet from mid- to late life can still be beneficial.

5. Conclusions

The present study identified associations between nutrition at midlife and the likelihood of healthy ageing in late life using robust data from cohort studies in Asia. Our study's results provide important evidence for policymaking and dietary guidelines aimed at promoting healthy ageing in Asia.
