**Abstract:** Novel Ag<sub>3</sub>PO<sub>4</sub>/Bi<sub>2</sub>WO<sub>6</sub> catalysts with enhanced visible-light performance were synthesized using a hydrothermal method and characterized to investigate their morphology, microscopic structure, and binding energies. Photoluminescence spectrum (PL) and electrochemical impedance spectroscopy (EIS) data demonstrate that the formed Ag<sub>3</sub>PO<sub>4</sub>/Bi<sub>2</sub>WO<sub>6</sub> heterojunction effectively promotes hole (h<sup>+</sup>)–electron (e<sup>−</sup>) separation and transfer efficiency, resulting in the enhancement of photocatalytic activity. Ag<sub>3</sub>PO<sub>4</sub>/Bi<sub>2</sub>WO<sub>6</sub> displays higher photocatalytic activity than pure Bi<sub>2</sub>WO<sub>6</sub> or Ag<sub>3</sub>PO<sub>4</sub> alone. Photogenerated holes (h<sup>+</sup>), ·O<sub>2</sub><sup>−</sup>, and ·OH were found to be the main active species for the degradation of malachite green (MG), methylene blue (MB), and Rhodamine B (RhB). The DFT calculation explains the photostability of Ag<sub>3</sub>PO<sub>4</sub>/Bi<sub>2</sub>WO<sub>6</sub> from the perspective of electronic structure. The bandgap of Ag<sub>3</sub>PO<sub>4</sub>/Bi<sub>2</sub>WO<sub>6</sub> between the highest occupied molecular orbital (HOMO) and the lowest unoccupied molecular orbital (LUMO) is 1.41 eV, compared with that of Ag<sub>3</sub>PO<sub>4</sub> at 0.91 eV and Bi<sub>2</sub>WO<sub>6</sub> at 2.59 eV. Ag–O–Bi hybridization and the wide HOMO–LUMO bandgap lead to difficulty in electron transfer. As a consequence, Ag<sup>+</sup> is difficult to obtain electrons and difficult to convert into Ag<sup>0</sup>, which makes the catalyst stable.

## 1. Introduction

In recent years, semiconductor photocatalysis has gained attention as an efficient and environmentally friendly technology for tackling current environmental issues. The photocatalytic process offers several benefits, including simplicity, energy efficiency, and the elimination of organic pollutants, without producing secondary pollution [1–4]. Conventional photocatalysts, including TiO<sub>2</sub> and ZnO, have been extensively researched for their ability to degrade organic pollutants [5]. However, they are limited to absorbing ultraviolet light and cannot fully utilize sunlight [6]. Recently, visible-light-response photocatalysts, such as Bi<sub>2</sub>WO<sub>6</sub>, BiOBr, BiVO<sub>4</sub>, Bi<sub>2</sub>O<sub>2</sub>CO<sub>3</sub>, Ag<sub>3</sub>PO<sub>4</sub>, AgBr, Ag<sub>3</sub>VO<sub>4</sub>, and AgCl, have been widely studied for their capacity to break down toxic dyes and organic pollutants [7–15]. Among these materials, Bi<sub>2</sub>WO<sub>6</sub> has garnered significant attention due to its capacity to degrade organic pollutants through visible-light irradiation [16–19]. However, its practical application is thwarted by its high recombination of h<sup>+</sup>–e<sup>−</sup> pairs and low absorption efficiency of visible light [20–22]. Similarly, the Ag<sub>3</sub>PO<sub>4</sub> photocatalyst reveals exceptional potential in photocatalytic processes for organic dye degradation under visible-light irradiation [23,24]. Furthermore, Ag<sub>3</sub>PO<sub>4</sub> is a viable option for creating heterostructure composites, effectively enhancing photocatalytic activity. Nevertheless, the overabundance of electrons in the valence band of Ag<sub>3</sub>PO<sub>4</sub> may lead to severe photo-corrosion by Ag<sup>+</sup> to Ag<sup>0</sup> [25]. Recently, various methods, including particle size and morphology control [26],

metal deposition modification, and doping, have been employed to enhance and optimize the photocatalytic activity and stability of  $\text{Ag}_3\text{PO}_4$ . One promising approach is the coupling of  $\text{Ag}_3\text{PO}_4$  with  $\text{Bi}_2\text{WO}_6$ . Maryam Amiri et al. developed a  $\text{Bi}_2\text{WO}_6/\text{Ag}_3\text{PO}_4$ -Ag Z-scheme heterojunction catalyst, which utilized the surface plasmon resonance (SPR) effect of Ag to increase photocatalytic activity and stability [27]. Sittikorn Jonjana et al. discovered that a 10 wt% mixture of  $\text{Ag}_3\text{PO}_4/\text{Bi}_2\text{WO}_6$  exhibited superior photocatalytic activity and stability compared with separate  $\text{Ag}_3\text{PO}_4$  or  $\text{Bi}_2\text{WO}_6$  samples. This finding highlights the lack of research focused on mixtures exceeding 10 wt% of the  $\text{Ag}_3\text{PO}_4/\text{Bi}_2\text{WO}_6$  system [28].

In this study, we present a straightforward hydrothermal and in situ precipitation approach to create a composite photocatalyst of  $\text{Ag}_3\text{PO}_4/\text{Bi}_2\text{WO}_6$  with a boosted  $\text{Ag}_3\text{PO}_4$  concentration. We evaluated the catalytic performance of the obtained samples, described the structural features, and examined the connections between the physicochemical characteristics and catalytic performance. Furthermore, we employed DFT to ascertain the grounds for the stability of  $\text{Ag}_3\text{PO}_4/\text{Bi}_2\text{WO}_6$  based on electronic structure analysis.

## 2. Materials and Methods

### 2.1. Reagents and Materials

All the reagents used in the experiment were of analytic grade and were commercially purchased without further purification.  $\text{AgNO}_3$ ;  $\text{NaH}_2\text{PO}_4 \cdot 3\text{H}_2\text{O}$ ;  $\text{Bi}(\text{NO}_3)_3 \cdot 5\text{H}_2\text{O}$ ;  $\text{Na}_2\text{WO}_4 \cdot 2\text{H}_2\text{O}$ ; Isopropyl alcohol (IPA); and MG, MB, and RhB were obtained from Sinopharm Chemical Reagent. Ammonium oxalate (AO) was purchased from Xilong Chemical Reagent, while p-benzoquinone (BQ) was obtained from Aladdin.

### 2.2. Preparation of Photocatalysts

In a typical procedure,  $\text{Bi}(\text{NO}_3)_3$  (2 mmol, 0.7899 g) was dissolved in 10 mL of glacial acetic acid and 10 mL of 2 mol/L  $\text{HNO}_3$  to prevent  $\text{Bi}^{3+}$  ion hydrolysis. Technical term abbreviations were explained when they were first used. Afterward, 1 mmol of  $\text{Na}_2\text{WO}_4$  (20 mL) solution was gradually added dropwise to the  $\text{Bi}(\text{NO}_3)_3$  solution. The mixture was continuously stirred for 4 h, then moved to a Teflon-coated autoclave and maintained at 160 °C for 20 h. Finally, it was cooled down to room temperature naturally. The  $\text{Bi}_2\text{WO}_6$  obtained was washed several times with deionized water to eliminate any residual by-products or reactants. It was then dried at 80 °C for 24 h. The dried powder was further calcined in a muffle oven at a temperature of 400 °C for 12 h with a temperature elevator of 5 °C/min.

$\text{Ag}_3\text{PO}_4/\text{Bi}_2\text{WO}_6$  composites were prepared using an in situ precipitation method. Typically, 0.6977 g (1 mmol) of the previously obtained  $\text{Bi}_2\text{WO}_6$  powder was dispersed into 40 mL of deionized water via ultrasound for 30 min. Next, 20 mL of  $\text{AgNO}_3$  solution (0.5096 g, 3 mmol) was added to the  $\text{Bi}_2\text{WO}_6$  dispersion. Subsequently, the mixture was stirred for an hour; then, 20 mL of  $\text{NaH}_2\text{PO}_4$  solution (0.1199 g, 1 mmol) was added dropwise with magnetic stirring. Finally, the resulting precipitate underwent washing with deionized water several times, centrifugation, and vacuum drying at 60 °C. Pure  $\text{Ag}_3\text{PO}_4$ ,  $\text{Bi}_2\text{WO}_6$ , and  $\text{Ag}_3\text{PO}_4/\text{Bi}_2\text{WO}_6$  mixed composites were also synthesized following identical procedures for comparative analysis.  $\text{Ag}_3\text{PO}_4/\text{Bi}_2\text{WO}_6$ -9 indicates that the mass proportion of  $\text{Ag}_3\text{PO}_4$  is 90%. Meanwhile,  $\text{Ag}_3\text{PO}_4/\text{Bi}_2\text{WO}_6$ -X with various mass proportions (90%, 80%, 70%, 60%, and 50%) was produced alike by controlling the  $\text{Ag}_3\text{PO}_4$  dose. The resulting products were labeled as  $\text{Ag}_3\text{PO}_4/\text{Bi}_2\text{WO}_6$ -X, where X equals 9, 8, 7, 6, and 5, respectively.

### 2.3. Characterization

The crystal phases and structures of the samples were analyzed via powder X-ray diffraction (XRD) utilizing a D/max-2550 PC (RIGAKU, Tokyo, Japan) equipped with  $\text{Cu K}\alpha$  ( $\lambda = 1.54056 \text{ \AA}$ ) radiation, set at 40 kV and 200 mA, and scanned from 15° to 85° at a rate of 6 °/min. The Thermo ESCALAB 250 X-ray photoelectron spectroscopy (XPS, Thermo Fisher Scientific, Waltham, MA, USA) was used to assess surface chemical compositions. Additionally, morphologies were examined using a Hi-tachi S-4800 field emission micro-

scope. The scanning electron microscope (FE-SEM) from Japan operated at 10 kilovolts for imaging. The High-Resolution Transmission Electron Microscopy (HR-TEM) images were obtained utilizing a JEOL JEM-2100F microscope from Tokyo, Japan. To determine the energy band structure of the photocatalysts, UV–visible Optical Diffuse Reflectance Spectra (DRS) were measured using  $\text{BaSO}_4$  as the background with a PerkinElmer Lambda850 instrument from MA, USA. The PerkinElmer LS55 MA USA's PL spectra, with an excitation wavelength of 360 nm, evaluated the  $\text{h}^+ - \text{e}^-$  pairs' recombination degree.

The CHI660E Electrochemical Workstation (CH Instruments, Shanghai, China) measured the photocatalyst's Electrochemical Impedance Spectroscopy (EIS) over a 100 Hz to 0.01 kHz frequency domain with a 5 mV perturbation potential. The EIS outcomes were fitted with Zview 3.0 software. The electrochemical electrode is constructed with a photocatalyst (approximately 3 mg in ethanol) deposition on an indium tin oxide glass, which serves as the working electrode. A Pt sheet acts as the counter electrode, a saturated calomel electrode (SCE) is used as the reference electrode, and a 0.1 M  $\text{Na}_2\text{SO}_4$  solution acts as the electrolyte solution. For slight and viscous suspension solutions, 3 mg sample powders mixed with Nafion ionomer were dissolved in an ethanol aqueous solution. The suspension was evenly applied onto the clean electrode surface composed of indium-tin oxide (ITO) through drop-coating and left to air dry, according to reference [23].

#### 2.4. Activity Test

Photocatalytic experiments were conducted using a slurry reaction reactor and a 500 W Xe lamp ( $300 \text{ mW}/\text{cm}^2$ ) from Perfectlight Technology Co., Ltd., Beijing, China, which was equipped with a cutoff filter ( $>400 \text{ nm}$ ) as a visible-light source. The target pollutants used were Malachite Green (MG), Methylene Blue (MB), and Rhodamine B (RhB) dye, and 20 mg of photocatalyst was dispersed into 50 mL of pollutant solution ( $C = 10 \text{ mg}/\text{L}$ , MG, MB, or RhB) under visible-light irradiation at  $25^\circ\text{C}$ . Before irradiation, the suspension was stirred continuously in the dark for 30 min to create a finely dispersed solution and establish adsorption–desorption equilibrium. While being irradiated, each 0.5 mL suspension was collected in a plastic sample tube containing 2.5 mL deionized water every 10 min and then centrifuged. The supernatant was analyzed using a T9 UV–vis spectrophotometer. Figure 1 depicts the schematic diagram of the photocatalytic reactor.

**Figure 1.** The schematic diagram of photocatalytic reactor.

#### 2.5. Calculation

DFT calculations were conducted using plane wave methods. We employed the Cambridge Sequential Total Energy Package (CASTEP) to perform the calculations. Our computational models consisted of tetragonal supercells ( $2 \times 2 \times 1$ ) of  $\text{Ag}_3\text{PO}_4$  and  $\text{Bi}_2\text{WO}_6$ . The Broyden–Fletcher–Goldfarb–Shanno (BFGS) algorithm was utilized to optimize the lattice constants and atomic coordinates in these supercells. Subsequently, after acquiring the stable structure, we calculated the electronic properties of both supercells. The study utilized Generalized Gradient Approximation (GGA) to express exchange and correlation effects, which were parameterized by the PBE function developed by Perdew–Burke–

Ernzerhof. Interactions between core and valence electrons were described using an ultrasoft pseudopotential. All geometry optimizations employ convergence thresholds of  $5 \times 10^{-6}$  eV/atom for total energies, a maximum force of 0.01 eV/Å, a maximum stress of 0.02 GPa, and a maximum displacement of  $5 \times 10^{-4}$  Å. Default values were utilized for other calculation parameters.

### 3. Results and Discussion

#### 3.1. Physicochemical Structure

Figure 2 displays X-ray diffraction (XRD) patterns for various  $\text{Ag}_3\text{PO}_4$ ,  $\text{Bi}_2\text{WO}_6$ , and  $\text{Ag}_3\text{PO}_4/\text{Bi}_2\text{WO}_6$  samples with varying ratios. The pure  $\text{Ag}_3\text{PO}_4$  exhibits a cubic phase (JCPDS: 06-0505). The diffraction peaks of  $\text{Ag}_3\text{PO}_4$  match crystal planes of (110), (200), (210), (211), (220), (310), (222), (320), (321), (400), (420), (421), and (332) at  $2\theta = 20.91^\circ$ ,  $29.75^\circ$ ,  $33.24^\circ$ ,  $36.46^\circ$ ,  $42.54^\circ$ ,  $47.80^\circ$ ,  $52.69^\circ$ ,  $54.87^\circ$ ,  $55.02^\circ$ ,  $61.58^\circ$ ,  $69.91^\circ$ ,  $71.88^\circ$ , and  $73.88^\circ$ , respectively, as depicted in Figure 2 [29]. The pure  $\text{Bi}_2\text{WO}_6$  crystal (JCPDS 39-0256) can be clearly identified as orthorhombic. The perfectly matching characteristic peaks at  $2\theta = 28.29^\circ$ ,  $32.79^\circ$ ,  $47.14^\circ$ ,  $55.99^\circ$ ,  $58.54^\circ$ ,  $68.75^\circ$ ,  $76.08^\circ$ , and  $78.53^\circ$  with  $\text{Bi}_2\text{WO}_6$  (JCPDS No. 39-0256, space group: Pbcn) can be indexed to the (131), (200), (202), (133), (262), (400), (193), and (204) crystal planes of orthorhombic  $\text{Bi}_2\text{WO}_6$  [30,31], respectively. All diffraction peaks of  $\text{Bi}_2\text{WO}_6$ ,  $\text{Ag}_3\text{PO}_4$ , and  $\text{Ag}_3\text{PO}_4/\text{Bi}_2\text{WO}_6$  composites exhibit a well-matched two-phase composition. None of the diffraction peaks for impurities like Ag,  $\text{Ag}_2\text{O}$ ,  $\text{Bi}_2\text{O}_3$ , or  $\text{WO}_3$  are observed. The strong and sharp peaks assigned to  $\text{Ag}_3\text{PO}_4/\text{Bi}_2\text{WO}_6$  composites display favorable crystal structures. Notably, the peak position of  $\text{Ag}_3\text{PO}_4$  remains relatively unchanged, indicating that  $\text{Bi}_2\text{WO}_6$  only adheres to the surface of  $\text{Ag}_3\text{PO}_4$  without penetrating the lattice.

**Figure 2.** The X-ray diffraction patterns obtained for the samples prepared with varying  $\text{Ag}_3\text{PO}_4/\text{Bi}_2\text{WO}_6$  ratios. The asterisk symbol (\*) indicates the  $\text{Bi}_2\text{WO}_6$  peak positions, while the diamond symbol (◆) represents the peak positions of  $\text{Ag}_3\text{PO}_4$ .

The SEM was used to characterize the morphology and microscopic structure of the as-prepared samples, including  $\text{Ag}_3\text{PO}_4$ ,  $\text{Bi}_2\text{WO}_6$ , and  $\text{Ag}_3\text{PO}_4/\text{Bi}_2\text{WO}_6$ . In Figure 3a,b,  $\text{Ag}_3\text{PO}_4$  exhibits cubic-shaped nanoparticles ranging between 100 and 400 nm in diameter,

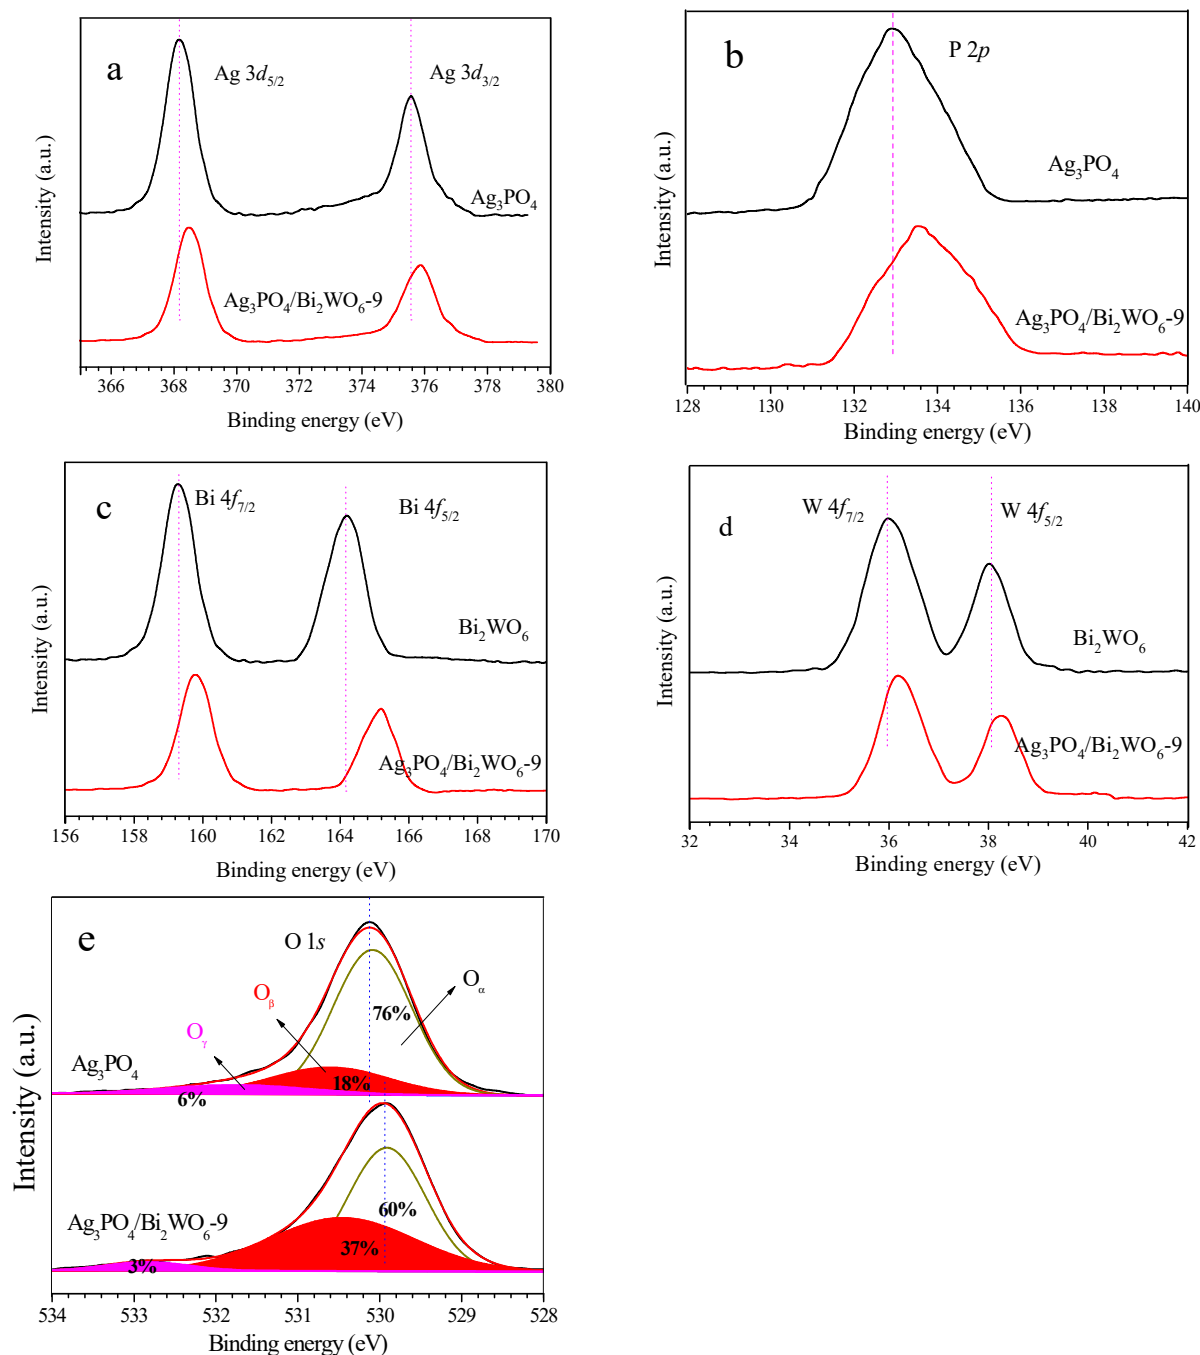

while the  $\text{Bi}_2\text{WO}_6$  sample presents an irregular cubical shape between 30 and 100 nm. The SEM image of  $\text{Ag}_3\text{PO}_4/\text{Bi}_2\text{WO}_6$ -9 shows that the  $\text{Bi}_2\text{WO}_6$  nanoparticle tightly adheres to the surface of  $\text{Ag}_3\text{PO}_4$  (Figure 3c). Figure 3d displays the TEM pattern of  $\text{Ag}_3\text{PO}_4/\text{Bi}_2\text{WO}_6$ -9. The regular shape of the material is  $\text{Ag}_3\text{PO}_4$ , while the amorphous shape is usually  $\text{Bi}_2\text{WO}_6$ . An amplified image of the local area can be found in Figure 3e, which highlights the heterojunction between  $\text{Ag}_3\text{PO}_4$  and  $\text{Bi}_2\text{WO}_6$  within a green frame. The magnified part of the interface is displayed in Figure 3f. Additionally, the HR-TEM pattern of  $\text{Ag}_3\text{PO}_4$  in  $\text{Ag}_3\text{PO}_4/\text{Bi}_2\text{WO}_6$ -9 heterojunction can be found in Figure 3g. The lattice fringe of 0.246 nm corresponds to the (211) plane of cubic  $\text{Ag}_3\text{PO}_4$  phase and coincides well with reported literature [32]. The HR-TEM image of  $\text{Bi}_2\text{WO}_6$  is shown in Figure 3h. The particle is confirmed to be  $\text{Bi}_2\text{WO}_6$  with space group B2cb [33] by the (200) crystal spacing (0.273 nm). In Figure S1, the elemental maps of  $\text{Ag}_3\text{PO}_4$ ,  $\text{Bi}_2\text{WO}_6$ , and  $\text{Ag}_3\text{PO}_4/\text{Bi}_2\text{WO}_6$ -9 demonstrate uniform distribution of all elements without agglomeration.

**Figure 3.** (a) SEM of  $\text{Ag}_3\text{PO}_4$ ; (b) SEM of  $\text{Bi}_2\text{WO}_6$ ; (c) SEM image of  $\text{Ag}_3\text{PO}_4/\text{Bi}_2\text{WO}_6$ -9; (d) TEM image of  $\text{Ag}_3\text{PO}_4/\text{Bi}_2\text{WO}_6$ -9; (e) magnified TEM image of  $\text{Ag}_3\text{PO}_4/\text{Bi}_2\text{WO}_6$ -9; (f) HR-TEM of  $\text{Ag}_3\text{PO}_4/\text{Bi}_2\text{WO}_6$ -9 heterojunction structure; (g) HR-TEM of  $\text{Ag}_3\text{PO}_4$  in  $\text{Ag}_3\text{PO}_4/\text{Bi}_2\text{WO}_6$ -9; (h) HR-TEM of  $\text{Bi}_2\text{WO}_6$  in  $\text{Ag}_3\text{PO}_4/\text{Bi}_2\text{WO}_6$ -9.

XPS was utilized to determine the electronic structures of  $\text{Ag}_3\text{PO}_4$ ,  $\text{Bi}_2\text{WO}_6$ , and  $\text{Ag}_3\text{PO}_4/\text{Bi}_2\text{WO}_6$ -9 composites. Figure 4a displays the XPS spectra of Ag 3d for both the  $\text{Ag}_3\text{PO}_4$  and  $\text{Ag}_3\text{PO}_4/\text{Bi}_2\text{WO}_6$ -9 composite catalysts. The characteristic peaks of Ag 3d at 368.0 eV ( $\text{Ag } 3d_{5/2}$ ) and 374.0 eV ( $\text{Ag } 3d_{3/2}$ ) are attributed to the  $\text{Ag}^+$  ions in  $\text{Ag}_3\text{PO}_4$ . After the introduction of  $\text{Bi}_2\text{WO}_6$ , the binding energy of spin-orbit Ag 3d splits into two peaks at 368.3 and 374.3 eV, which is 0.3 eV higher than that of  $\text{Ag}_3\text{PO}_4$ . This indicates that the electronic clouds on  $\text{Ag}^+$  in  $\text{Ag}_3\text{PO}_4$  shift to  $\text{Bi}_2\text{WO}_6$  after combination. Furthermore, compared with pure  $\text{Ag}_3\text{PO}_4$ , the binding energy of P 2p in  $\text{Ag}_3\text{PO}_4/\text{Bi}_2\text{WO}_6$ -9 is higher, with a value of 133.7 eV instead of 132.9 eV (Figure 4b). The peaks observed at 159.4 eV and 164.7 eV correspond to the Bi 4f<sub>7/2</sub> and Bi 4f<sub>5/2</sub> sublevels of  $\text{Bi}_2\text{WO}_6$ , respectively. On

the other hand, the peaks at 159.9 eV and 165.2 eV are associated with the Bi  $4f_{7/2}$  and Bi  $4f_{5/2}$  levels of  $\text{Ag}_3\text{PO}_4/\text{Bi}_2\text{WO}_6$ , respectively, suggesting that the bismuth species in the composite are  $\text{Bi}^{3+}$  cations. Furthermore, the peaks observed at 35.98 eV and 37.98 eV for the W  $4f_{7/2}$  and W  $4f_{5/2}$  sublevels, respectively, can be attributed to a six-valent oxidation state for  $\text{W}^{6+}$  in  $\text{Ag}_3\text{PO}_4/\text{Bi}_2\text{WO}_6$ . These findings indicate a 0.18 eV deviation of  $4f_{7/2}$  and  $4f_{5/2}$  levels relative to the values in pure  $\text{Bi}_2\text{WO}_6$  (refer to Figure 4d for more details).

**Figure 4.** XPS spectra of the catalysts. (a) Ag 3p; (b) P 2p; (c) Bi 4f; (d) W 4f; (e) O 1s.

The O 1s XPS spectra for the samples are presented in Figure 4e. The spectra for  $\text{Ag}_3\text{PO}_4$  indicate three distinct peaks with binding energies of 530.1 eV (identified as  $\text{O}_\alpha$ ), 531.6 eV (531.3 eV, identified as  $\text{O}_\beta$ ), and 533.1 eV (533.1 eV, identified as  $\text{O}_\gamma$ ). These peaks are attributed to lattice oxygen, adsorbed oxygen species, and defect oxygen located on the surface of  $\text{Ag}_3\text{PO}_4$ , respectively [33–35]. In the case of  $\text{Ag}_3\text{PO}_4/\text{Bi}_2\text{WO}_6$ -9, the binding

energies for O 1s orbits are 529.9 eV, 531.4 eV, and 532.8 eV. The composites also exhibit significantly lower energy shifts compared to their individual constituents. It is apparent that the  $(O_{\beta} + O_{\gamma})/O_{\alpha}$  ratio of  $Ag_3PO_4$  (24%:76%) is appreciably lower than that of the  $Ag_3PO_4/Bi_2WO_6$ -9 composite (40%:60%). The augmented ratio of active oxygen ( $O_{\beta} + O_{\gamma}$ ) is beneficial in enhancing photocatalytic performance. The chemical interactions between  $Bi_2WO_6$  and  $Ag_3PO_4$  have resulted in variations in the binding energies of Ag 3d, P 2p, Bi 4f, W 4f, and O 1s, indicating the formation of heterostructures and the promotion of interfacial charge transfer. As a result, the photocatalytic activity of  $Ag_3PO_4/Bi_2WO_6$  nanocomposites has improved. An increase in binding energy typically leads to the loss of an atom's charge and a subsequent decrease in the density of the surrounding electron cloud. This reduction enhances the attraction between the nucleus and electrons, thereby increasing the electron binding energy. This leads to an increase in reactive oxygen species and a decrease in electron density of  $Ag^+$  ions, ultimately improving the catalytic performance and stability of  $Ag_3PO_4$ .

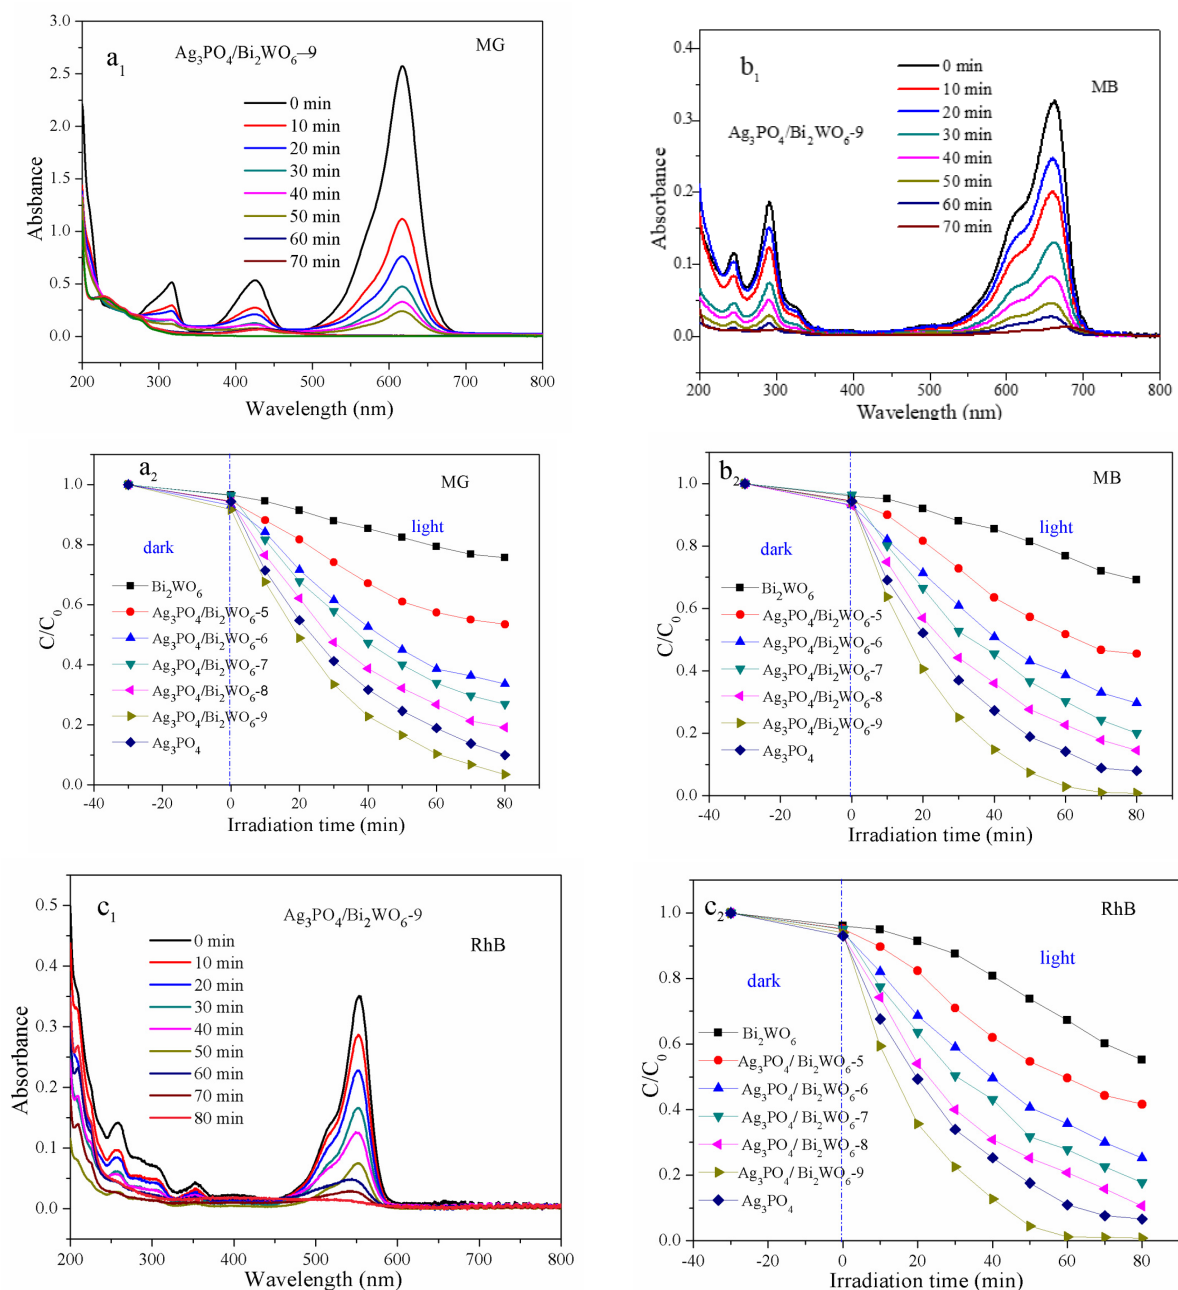

UV–vis DRS was conducted to examine the optical properties of relevant samples. All samples displayed visible-light absorbance. Figure S2 displays the results of UV–vis DRS for  $Bi_2WO_6$ ,  $Ag_3PO_4$ , and  $Ag_3PO_4/Bi_2WO_6$  with differing composite ratios.  $Ag_3PO_4/Bi_2WO_6$  exhibits varying absorption band edges according to the composite ratio. The composites demonstrate notable absorption within the visible-light range ( $760\text{ nm} > \lambda > 400\text{ nm}$ ). In Figure 5, the fundamental absorption band edge of pure  $Bi_2WO_6$  is measured at 459 nm. Additionally, the strong absorption band edge of  $Ag_3PO_4$  is observed at approximately 523 nm, in line with previous findings [29]. The absorption of the composite material  $Ag_3PO_4/Bi_2WO_6$ -9 demonstrates infrared transfer to 493 nm compared with  $Bi_2WO_6$ . Based on Figure 5a, the direct optical band gap energies ( $E_g$ ) of pure  $Bi_2WO_6$ ,  $Ag_3PO_4$ , and  $Ag_3PO_4/Bi_2WO_6$ -9 composites are estimated at 2.70, 2.37, and 2.51 eV, respectively. Tauc plots of  $Bi_2WO_6$ ,  $Ag_3PO_4$ , and  $Ag_3PO_4/Bi_2WO_6$ -9 are displayed in Figure 5b for better comprehension. This demonstrates the formation of heterostructure in  $Ag_3PO_4/Bi_2WO_6$ -9.

**Figure 5.** (a) UV–vis DRS of as-synthesized samples of  $Bi_2WO_6$ ,  $Ag_3PO_4$ , and  $Ag_3PO_4/Bi_2WO_6$ -9. (b) Tauc plots of  $Bi_2WO_6$ ,  $Ag_3PO_4$ , and  $Ag_3PO_4/Bi_2WO_6$ -9.

### 3.2. Photocatalytic Performance under Visible-Light Irradiation

The catalytic performances of visible-light-driven catalysts were evaluated through the degradation of aqueous dyes with different structures, including triphenylmethane MG, phenothiazine group MB, and triphenyl RhB. To ensure adsorption–desorption equilibrium, the mixture containing dye solution and catalyst was kept in the dark for 30 min before irradiation. As depicted in Figure 6(a<sub>1</sub>,b<sub>1</sub>,c<sub>1</sub>),  $Ag_3PO_4/Bi_2WO_6$ -9 shows a good adsorption capacity for MG, MB, and RhB.

**Figure 6.** (1) Time-dependent UV-vis absorption spectra of the MG (a<sub>1</sub>), MB (b<sub>1</sub>), and RhB (c<sub>1</sub>) solution in the presence of Ag<sub>3</sub>PO<sub>4</sub>/Bi<sub>2</sub>WO<sub>6</sub>-9. (2) Degradation curves of MG (a<sub>2</sub>), MB (b<sub>2</sub>), and RhB (c<sub>2</sub>) with Ag<sub>3</sub>PO<sub>4</sub>, Bi<sub>2</sub>WO<sub>6</sub>, and Ag<sub>3</sub>PO<sub>4</sub>/Bi<sub>2</sub>WO<sub>6</sub> composites under visible-light irradiation.

Figure 6(a<sub>2</sub>, b<sub>2</sub>, c<sub>2</sub>) display the decolorization efficiencies of Ag<sub>3</sub>PO<sub>4</sub>/Bi<sub>2</sub>WO<sub>6</sub>-X (X = 5, 6, 7, 8, 9), pure Ag<sub>3</sub>PO<sub>4</sub>, and Bi<sub>2</sub>WO<sub>6</sub> for the dyes MG, MB, and RhB. The activity of these catalysts follows the trend of Bi<sub>2</sub>WO<sub>6</sub> < Ag<sub>3</sub>PO<sub>4</sub>/Bi<sub>2</sub>WO<sub>6</sub>-5 < Ag<sub>3</sub>PO<sub>4</sub>/Bi<sub>2</sub>WO<sub>6</sub>-6 < Ag<sub>3</sub>PO<sub>4</sub>/Bi<sub>2</sub>WO<sub>6</sub>-7 < Ag<sub>3</sub>PO<sub>4</sub>/Bi<sub>2</sub>WO<sub>6</sub>-8 < Ag<sub>3</sub>PO<sub>4</sub> < Ag<sub>3</sub>PO<sub>4</sub>/Bi<sub>2</sub>WO<sub>6</sub>-9 for the three dyes. The photocatalytic activity of the Ag<sub>3</sub>PO<sub>4</sub>/Bi<sub>2</sub>WO<sub>6</sub>-9 composite displays the best catalytic performance.

The stability of Ag<sub>3</sub>PO<sub>4</sub> and Ag<sub>3</sub>PO<sub>4</sub>/Bi<sub>2</sub>WO<sub>6</sub>-9 was assessed by studying the degradation of RhB dyes under visible-light irradiation (see Figure 7). Following five cycles of the photodegradation process, the degradation efficiency of Ag<sub>3</sub>PO<sub>4</sub> decreased from 86% to 30%. In contrast, the degradation efficiency of Ag<sub>3</sub>PO<sub>4</sub>/Bi<sub>2</sub>WO<sub>6</sub>-9 decreased from 97% to 76%, indicating that Ag<sub>3</sub>PO<sub>4</sub>/Bi<sub>2</sub>WO<sub>6</sub>-9 displays little activity loss and good photo-

chemical stability. In contrast, the degradation efficiency of  $\text{Ag}_3\text{PO}_4/\text{Bi}_2\text{WO}_6$ -9 decreased from 97% to 76%, indicating that  $\text{Ag}_3\text{PO}_4/\text{Bi}_2\text{WO}_6$ -9 displays little activity loss and good photochemical stability.

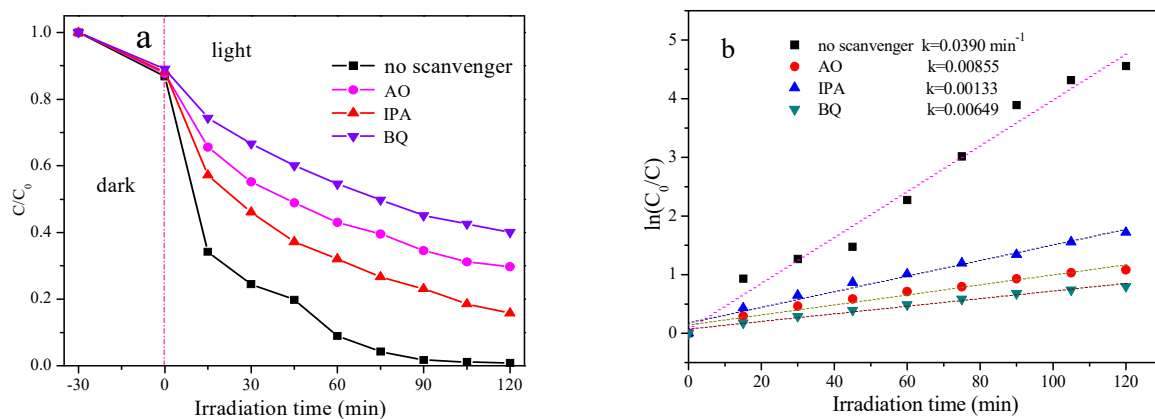

**Figure 7.** Photocatalytic cycle performance of  $\text{Ag}_3\text{PO}_4$  and  $\text{Ag}_3\text{PO}_4/\text{Bi}_2\text{WO}_6$ -9.

### 3.3. The Relationship of Structure and Activity

#### 3.3.1. Main Free Radicals

$\text{Ag}_3\text{PO}_4/\text{Bi}_2\text{WO}_6$ -9 was utilized to photodegrade RhB, and scavengers—namely, AO, IPA, and BQ—were applied to test the  $\cdot\text{OH}$ ,  $\text{h}^+$ , and  $\cdot\text{O}_2^-$  free radicals, correspondingly. Photodegradation efficiencies with different scavengers are presented in Figure 8a. Notably, the efficiency of  $\text{Ag}_3\text{PO}_4/\text{Bi}_2\text{WO}_6$ -9 without any scavengers is high, while the efficiencies decrease after adding scavengers. Figure 8b displays the reaction rate constant  $k$ . Based on the aforementioned results, the primary free radicals were  $\cdot\text{OH}$ , while the other free radicals consisted of  $\cdot\text{O}_2^-$  and hole. These highly reactive free radicals are potentially accountable for the deterioration of RhB.

**Figure 8.** Photodegradation efficiencies of RhB as a function of irradiation time with different scavengers. (a) Photodegradation efficiencies with different scavengers. (b) Reaction rate constants  $k$  with different scavengers.

#### 3.3.2. PL Analysis

Figure S3 displays the photoluminescence (PL) spectra of  $\text{Ag}_3\text{PO}_4$ ,  $\text{Ag}_3\text{PO}_4/\text{Bi}_2\text{WO}_6$ -5,  $\text{Ag}_3\text{PO}_4/\text{Bi}_2\text{WO}_6$ -6,  $\text{Ag}_3\text{PO}_4/\text{Bi}_2\text{WO}_6$ -7,  $\text{Ag}_3\text{PO}_4/\text{Bi}_2\text{WO}_6$ -8,  $\text{Ag}_3\text{PO}_4/\text{Bi}_2\text{WO}_6$ -9, and  $\text{Bi}_2\text{WO}_6$  composites. The PL intensities follow the order  $\text{Bi}_2\text{WO}_6 > \text{Ag}_3\text{PO}_4/\text{Bi}_2\text{WO}_6$ -5  $> \text{Ag}_3\text{PO}_4/\text{Bi}_2\text{WO}_6$ -6  $> \text{Ag}_3\text{PO}_4/\text{Bi}_2\text{WO}_6$ -7  $> \text{Ag}_3\text{PO}_4/\text{Bi}_2\text{WO}_6$ -8  $> \text{Ag}_3\text{PO}_4/\text{Bi}_2\text{WO}_6$ -9  $> \text{Ag}_3\text{PO}_4$ . The PL intensity of the  $\text{Ag}_3\text{PO}_4/\text{Bi}_2\text{WO}_6$ -9 composite exhibits an obvious

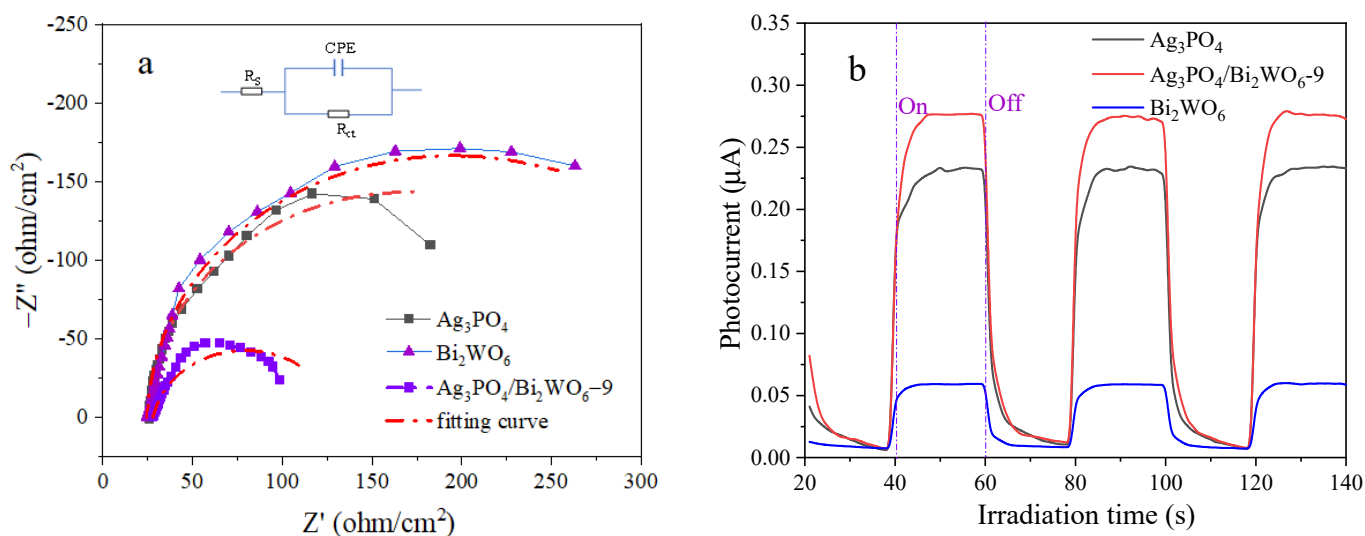

decrease compared with pure  $\text{Bi}_2\text{WO}_6$  (as shown in Figure 9). The  $\text{Ag}_3\text{PO}_4/\text{Bi}_2\text{WO}_6$ -9 composite exhibits a decreased PL intensity compared with  $\text{Ag}_3\text{PO}_4$  and  $\text{Bi}_2\text{WO}_6$ , suggesting efficient inhibition of photoexcited electron–hole recombination through the formation of the  $\text{Ag}_3\text{PO}_4/\text{Bi}_2\text{WO}_6$  heterojunction.

**Figure 9.** PL spectra of  $\text{Bi}_2\text{WO}_6$ ,  $\text{Ag}_3\text{PO}_4$ , and  $\text{Ag}_3\text{PO}_4/\text{Bi}_2\text{WO}_6$ -9 composites.

### 3.3.3. EIS Analysis

EIS was utilized to examine the charge transfer resistance and segregation of photogenerated  $\text{h}^+e^-$  pairs at solid/electrolyte interfaces in the photocatalyst. Figure 10 illustrates the EIS Nyquist plots of  $\text{Ag}_3\text{PO}_4$ ,  $\text{Bi}_2\text{WO}_6$ , and  $\text{Ag}_3\text{PO}_4/\text{Bi}_2\text{WO}_6$ -9 blends under visible-light irradiation. The corresponding circuit model employed to fit the obtained data is included, where  $R_s$  indicates solution resistance, CPE denotes the constant phase angle element, and  $R_{ct}$  refers to reaction resistance. This is indicated by the smallest arc radius belonging to  $\text{Ag}_3\text{PO}_4/\text{Bi}_2\text{WO}_6$ -9. In Figure 10a, the EIS plot shows that  $\text{Ag}_3\text{PO}_4/\text{Bi}_2\text{WO}_6$ -9 had the fastest interfacial electron transfer and more separation of photogenerated  $\text{h}^+e^-$  pairs compared with  $\text{Bi}_2\text{WO}_6$  and  $\text{Ag}_3\text{PO}_4$ . The simulated data can be found in Table S1. The combination of PL and EIS data indicates that creating a  $\text{Ag}_3\text{PO}_4/\text{Bi}_2\text{WO}_6$  heterojunction effectively enhances charge separation and transfer efficiency, consequently resulting in an improvement in photocatalytic activity.

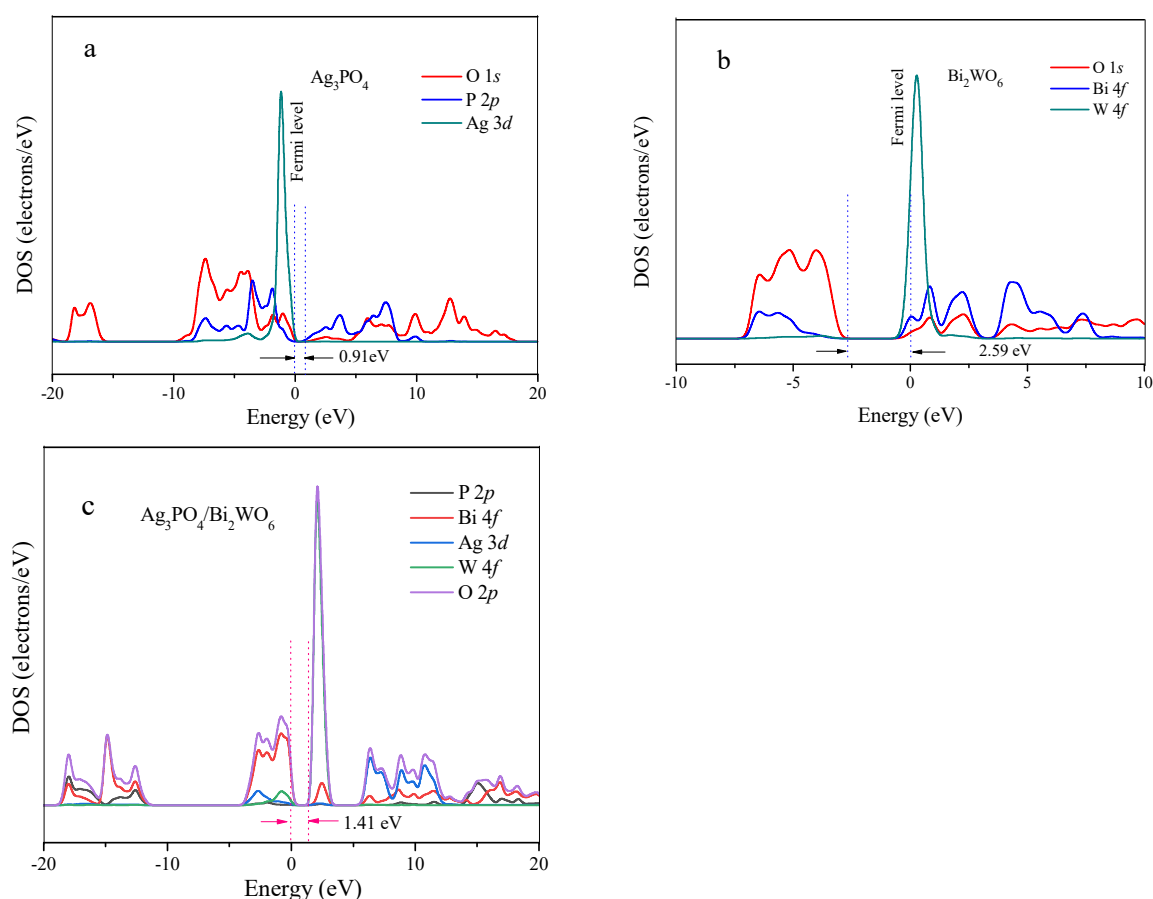

**Figure 10.** (a) EIS plots of the samples under irradiation with visible light. Insert: equivalent circuit used to fit the data; (b) transient photocurrent response curves for the three catalysts.

Figure 10b illustrates the transient photocurrent response of the three catalysts, measured over several intermittent irradiation cycles. Upon activation, the photocurrent rapidly increases to a stable current platform, which subsequently falls back to a small value once deactivated. Notably, the photocurrent observed for  $\text{Ag}_3\text{PO}_4/\text{Bi}_2\text{WO}_6$  is the largest, followed by  $\text{Ag}_3\text{PO}_4$ , while that of  $\text{Bi}_2\text{WO}_6$  is the smallest. These results suggest that more electrons and holes in  $\text{Ag}_3\text{PO}_4/\text{Bi}_2\text{WO}_6$  are excited, whereby they subsequently participate in the photocatalytic degradation reaction.

### 3.3.4. DFT Analysis

To elucidate the electronic states of the catalytically active sites (CASs) in  $\text{Ag}_3\text{PO}_4/\text{Bi}_2\text{WO}_6$ , the density of states (DOS) of  $\text{Ag}_3\text{PO}_4$ ,  $\text{Bi}_2\text{WO}_6$ , and  $\text{Ag}_3\text{PO}_4/\text{Bi}_2\text{WO}_6$  were calculated using DFT. Figure S4 illustrates simplified models (unit cell) depicting the crystal structures of  $\text{Ag}_3\text{PO}_4$  (Figure S4a) and  $\text{Bi}_2\text{WO}_6$  (Figure S4b), with different elements represented by distinct colors. The simplified models are solely utilized to demonstrate the bonding environment of  $\text{Ag}_3\text{PO}_4$  and  $\text{Bi}_2\text{WO}_6$ . By optimizing the lattice constants, the  $\text{Ag}_3\text{PO}_4$  and  $\text{Bi}_2\text{WO}_6$  supercells have dimensions of  $6.026 \text{ \AA} \times 6.026 \text{ \AA} \times 6.026 \text{ \AA}$  and  $5.5340 \text{ \AA} \times 5.4998 \text{ \AA} \times 16.5507 \text{ \AA}$ , respectively. Technical terms are clearly explained when first used. Each P atom coordinates with four O atoms, and each O atom coordinates with one P atom and three Ag atoms in  $\text{Ag}_3\text{PO}_4$  (Figure 11a).

**Figure 11.** The DOS patterns. (a)  $\text{Ag}_3\text{PO}_4$ ; (b)  $\text{Bi}_2\text{WO}_6$ ; (c)  $\text{Ag}_3\text{PO}_4/\text{Bi}_2\text{WO}_6$ .

The DOS of O 1s, P 2p, and Ag 3d appear in the same energy regions, indicating the presence of Ag-O and P-O hybridization. The bandgap between the HOMO and LUMO is approximately 0.91 eV. Mixing with  $\text{Bi}_2\text{WO}_6$  (Figure 11b) caused an increase in the bandgap to 1.41 eV due to the upshift of HOMO energy (Figure 11c). This tendency is consistent with experimental results showing that the band gap energies of pure  $\text{Ag}_3\text{PO}_4$ ,  $\text{Bi}_2\text{WO}_6$ ,

and  $\text{Ag}_3\text{PO}_4/\text{Bi}_2\text{WO}_6$  composites are 2.37, 2.7, and 2.51 eV, respectively. Therefore, due to the hybridization between Ag, O, and Bi, and the wide bandgap between the HOMO and LUMO, the transfer of electrons through bridging O between Ag and Bi may be hindered, resulting in difficulty obtaining electrons to reduce  $\text{Ag}^+$  into  $\text{Ag}^0$ . Additionally, there is implicit hybridization between Bi and W cations through their interactions with bridging O atoms, as the DOS of Bi, O, and W in  $\text{Bi}_2\text{WO}_6$  are in similar energy regimes. Due to the hybridization of Bi–O–W and the wide bandgap between the HOMO and LUMO, the transfer of electrons between W and Bi through the bridging O is expected to become relatively easy, resulting in the co-existence of multiple oxidation states of W and Bi. The composite  $\text{Ag}_3\text{PO}_4/\text{Bi}_2\text{WO}_6$  increases the bandgap between the HOMO and LUMO, thereby enhancing the catalytic activity of the active O and improving the photostability of  $\text{Ag}_3\text{PO}_4$ .

### 3.3.5. Proposed Photocatalytic Degradation Mechanism

Based on the experimental data and literature review, we propose a mechanism for photocatalysis under visible-light irradiation (see Figure 12). When the catalyst is exposed to visible light, the electrons in the valence band (VB) of  $\text{Ag}_3\text{PO}_4$  become excited and move to its conduction band (CB) orbital. Consequently, holes are formed in the VB of  $\text{Ag}_3\text{PO}_4$ , while the CB orbital of  $\text{Ag}_3\text{PO}_4$  becomes occupied by electrons. The same behavior is observed in  $\text{Bi}_2\text{WO}_6$ . The efficient heterojunction between  $\text{Ag}_3\text{PO}_4$  and  $\text{Bi}_2\text{WO}_6$  results from the transfer of holes from  $\text{Bi}_2\text{WO}_6$  to the VB orbital of  $\text{Ag}_3\text{PO}_4$  and the migration of electrons from  $\text{Ag}_3\text{PO}_4$  to the CB orbital of  $\text{Bi}_2\text{WO}_6$ . This can be attributed to the lower VB energy level of  $\text{Ag}_3\text{PO}_4$  compared with that of  $\text{Bi}_2\text{WO}_6$ . Thus, the two materials are tightly bonded together. Furthermore, the dissolved oxygen molecules in water scavenge the electrons present on  $\text{Ag}_3\text{PO}_4$  CB and produce highly oxidative  $\cdot\text{O}_2^-$  species, which could react with  $\text{H}_2\text{O}$  to generate  $\cdot\text{OH}$ . The hole  $h^+$  also produces  $\cdot\text{OH}$  after reacting with water, while the formed  $\cdot\text{OH}$ ,  $\cdot\text{O}_2^-$ , and  $h^+$  effectively break down organic substrates.

**Figure 12.** Schematic diagram of the separation and transfer of photogenerated charges in the hybrid under visible-light irradiation.

#### 4. Conclusions

A novel visible-light-driven photocatalyst composed of  $\text{Ag}_3\text{PO}_4/\text{Bi}_2\text{WO}_6$  composites was synthesized and characterized successfully. X-ray diffraction analysis demonstrated that the  $\text{Ag}_3\text{PO}_4/\text{Bi}_2\text{WO}_6$  composites possess crystal structures. The morphology and microscopic structures of  $\text{Ag}_3\text{PO}_4/\text{Bi}_2\text{WO}_6$  were observed through scanning and transmission electron microscopy. X-ray photoelectron spectroscopy exhibited that the catalytic performance and stability of  $\text{Ag}_3\text{PO}_4$  improved due to an increase in reactive oxygen species and a decrease in the electron density of  $\text{Ag}^+$  ions. The  $\text{Ag}_3\text{PO}_4/\text{Bi}_2\text{WO}_6$  composites prepared demonstrate superior photodegradation activity for degrading MG, MB, and RhB in comparison with  $\text{Bi}_2\text{WO}_6$  or  $\text{Ag}_3\text{PO}_4$  under visible-light irradiation. The improved activity can be attributed to the effective separation of electron–hole pairs generated by light and the production of free radicals such as  $\cdot\text{OH}$ ,  $\cdot\text{O}_2^-$ , and  $\text{h}^+$ .
