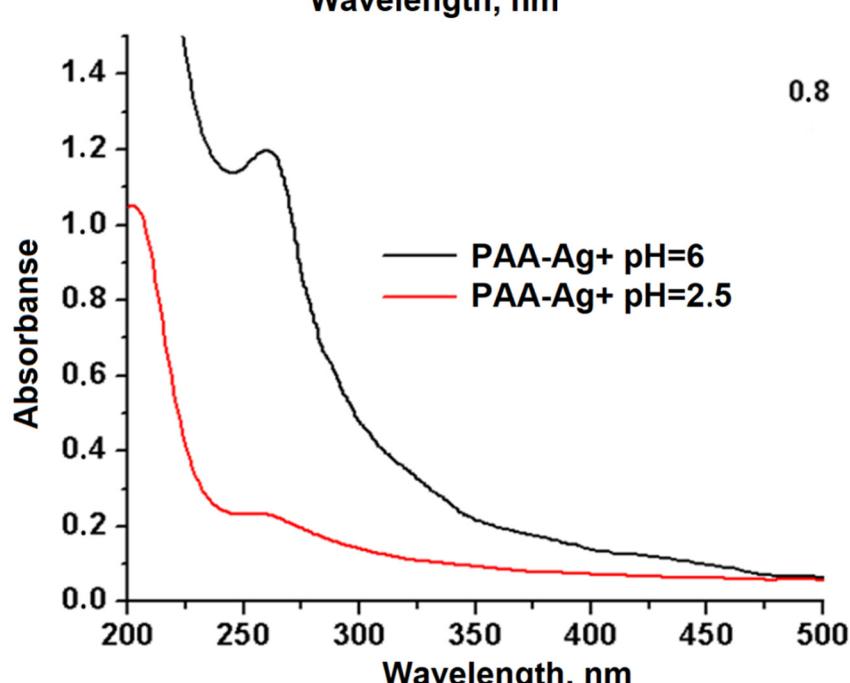

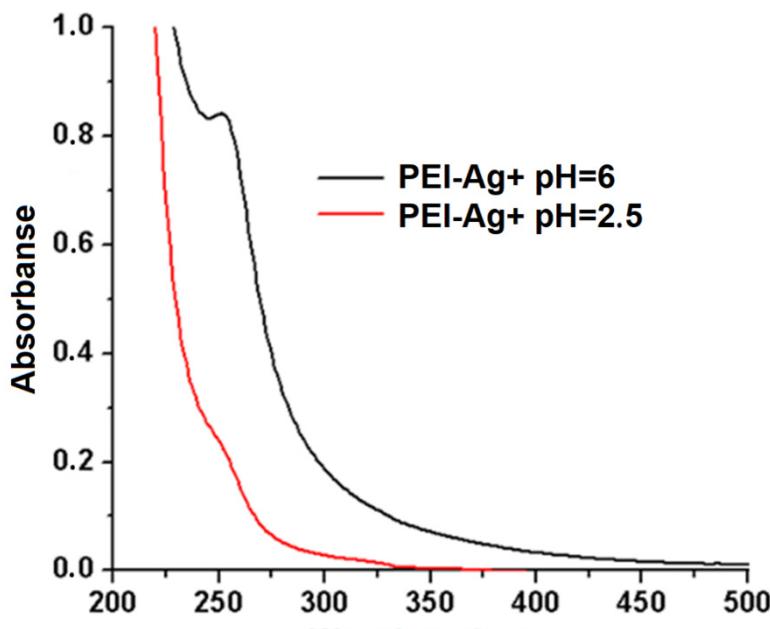

Figure S1. UV-Vis spectra solutions of PEI (a); PAA (b) with Ag^+ ions at pH=6.0 and pH=2.5. Increase of acidity lead to dramatically decrease of the intensity of these signals, which indicates that most silver ions are in the form of aquacomplexes.

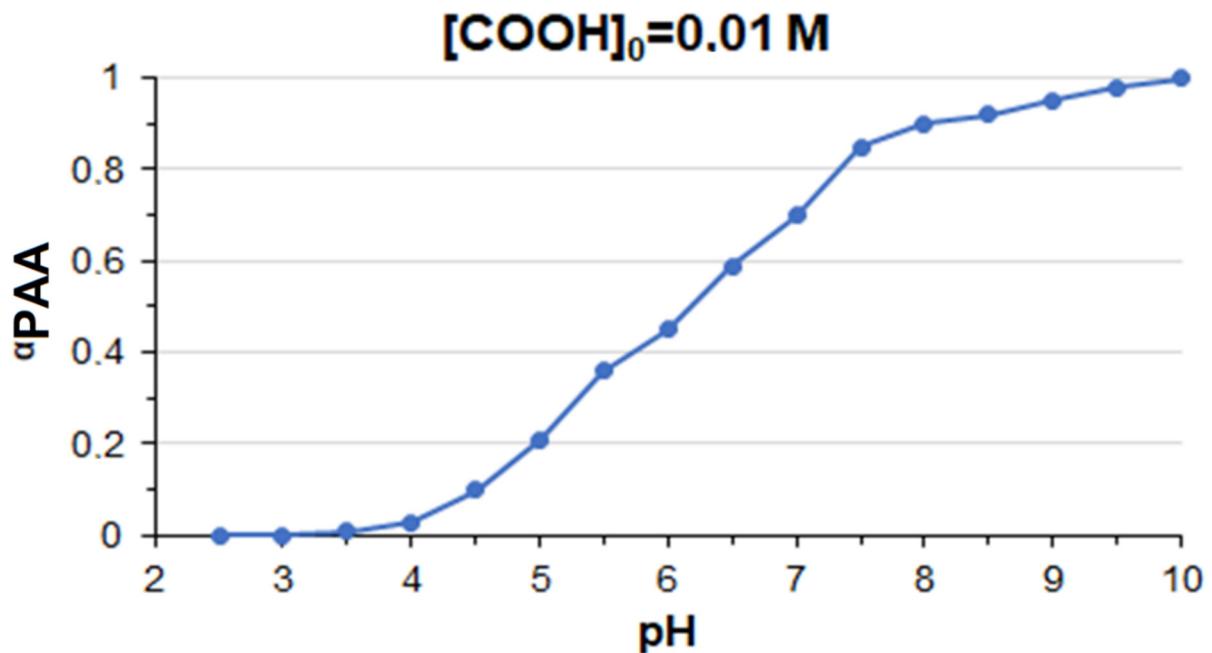

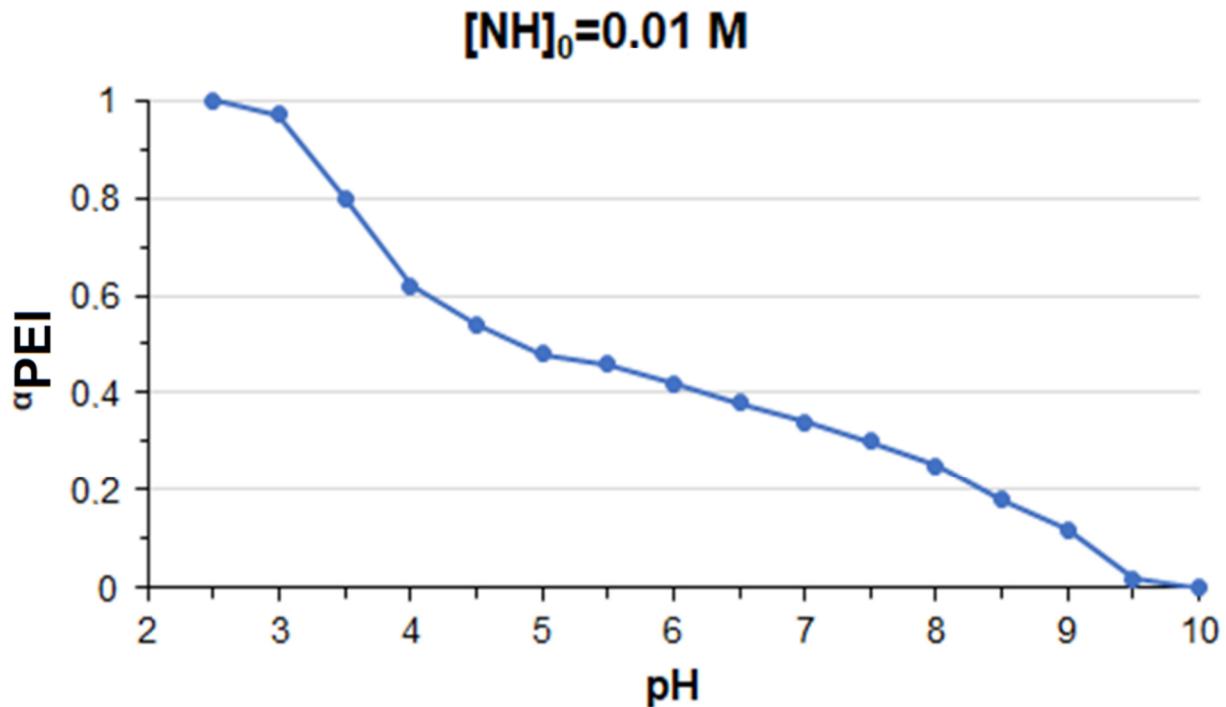

Figure S2. Dependence of the degree of protonation PEI (α_{PEI}) on $\text{p}\varnothing$ (a), dependence of the degree of dissociation PAA (α_{PAA}) on $\text{p}\varnothing$. Obviously, the maximum number of salt bonds will occur at those $\text{p}\varnothing$ values at which both polymer components carry a significant charge, that is, at $5 \leq \text{p}\varnothing \leq 7$.

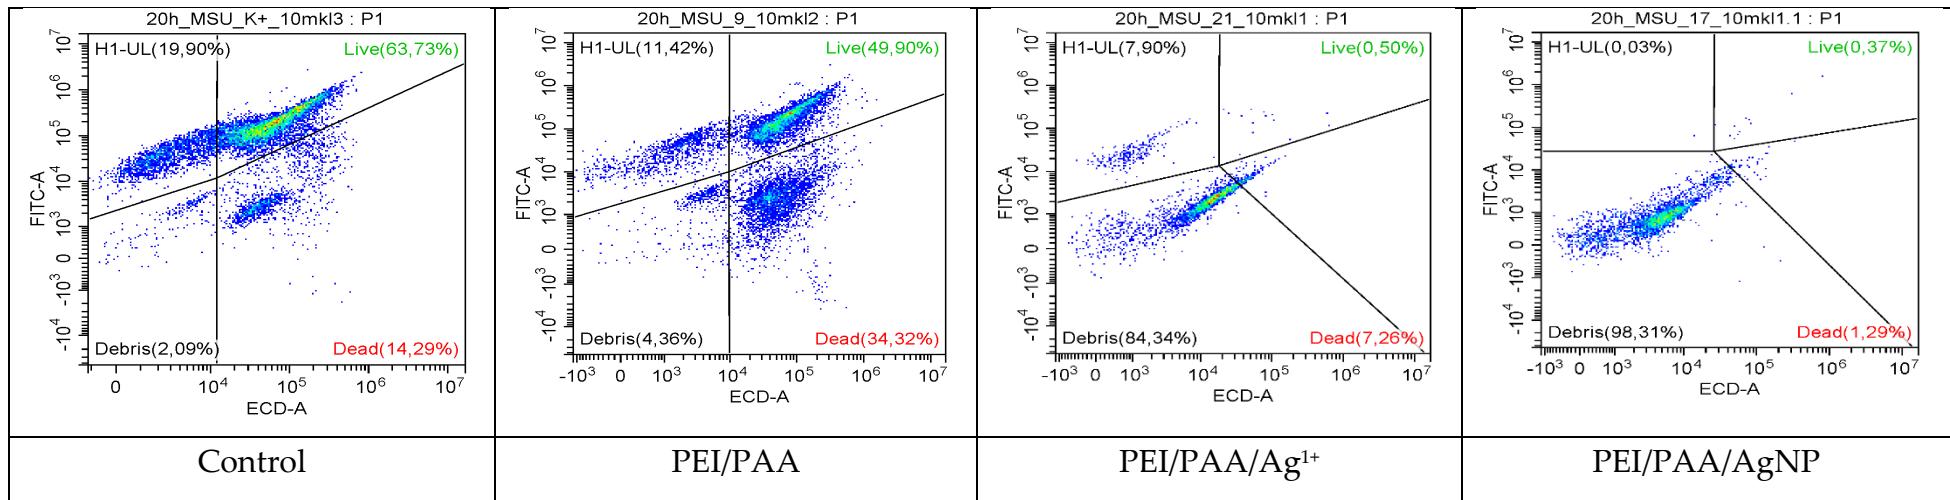

Figure S3. Flow cytograms demonstrating antimicrobial activity against *S. aureus* after 20 hours of incubation.

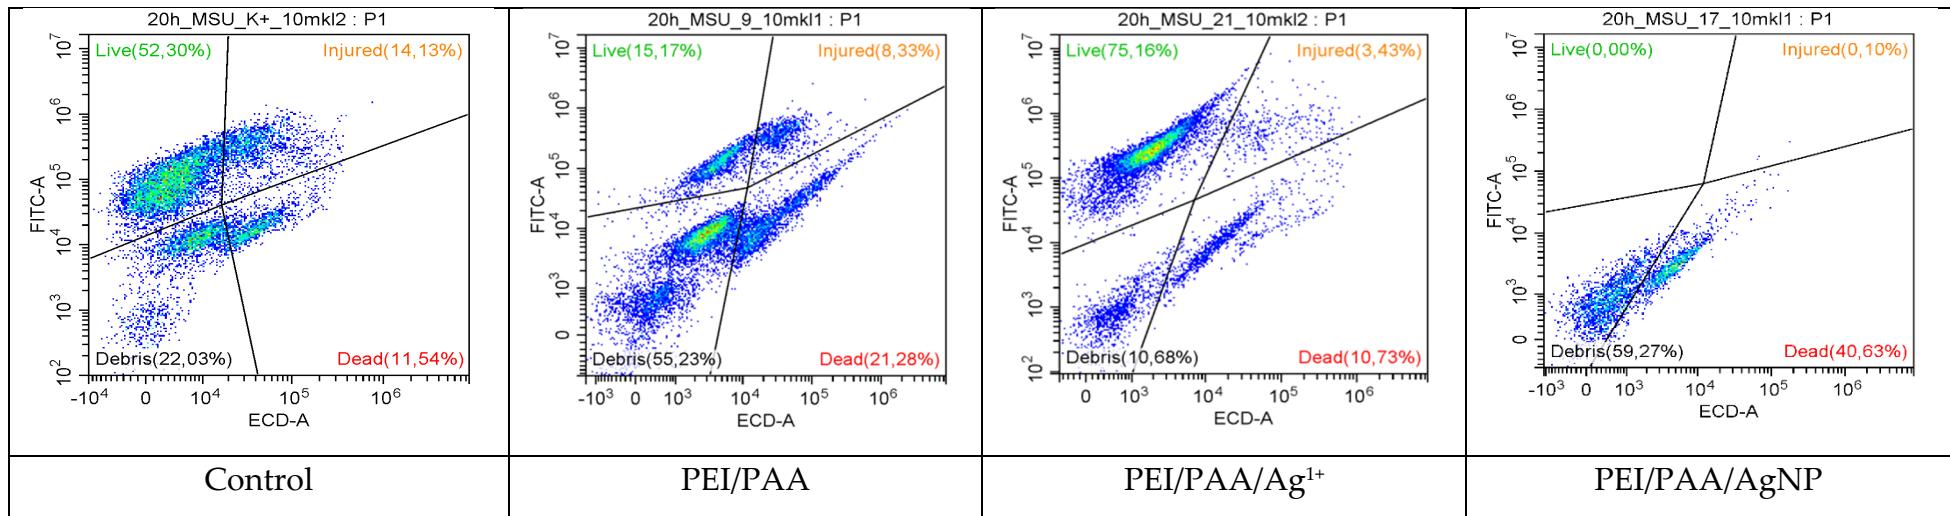

Figure S4. Flow cytograms demonstrating antimicrobial activity against *P. aeruginosa* after 20 hours of incubation.

Table S1. DLS data for interpolyelectrolyte and metal polymer complexes of PEI – PAA.

System	Def, nm	PDI	EPM, ($\mu\text{m/s}$)/(V/cm)	Zp, mV
PEI-PAA	230	0.2	+2.01 ± 0.13	+25.68 ± 1.69
PEI-PAA-Ag ⁺	200	0.2	+1.78 ± 0.12	+22.75 ± 1.52

Particles of interpolyelectrolyte complexes and metal polymer complexes of branched PEI ((Mw = 60,000) and linear PAA ((Mw = 100,000) are formed with close sizes and a relatively wide size distribution.
