The Chi square test for Hardy-Weinberg (HWE), using two degrees of freedom, was calculated in both sexes according to the following alleles and genotypes: in males, p and q are the number of males carrying respectively allele, while in female, p^2, $2pq$ and q^2 are the number of females carrying one of the probable respectively genotype. Two times analysis conducted by directly statistical analysis [25] and Haploview software, version 4.2.
