1. Measurement of fuel density

2. Supplementary Tables

3. Supplementary Figures

1. Measurement of fuel density

There is no standard method for the measurement of density of firewood logs. In this work, we used a new method to measure the density of wood logs by measuring the mass and volume of the pieces of firewood logs by dipping them into the fully filled beaker. We measured both the dry and wet mass of the wood log and subtracted from wet to dry mass to calculate the water mass sucked into the log. We also measured the mass of overflow water and residual water in the beaker after the wood log is soaked and taken out of the beaker. Then, we calculated actual mass of wood log by subtracting residual water mass and water mass sucked into the log from the full volume of the water mass in the beaker, which is the volume of wood log. Finally, the density of the wood log is calculated by dividing the wood volume by the dry mass of wood.

2. Supplementary tables

A schematic of the test procedure and wood species used in tests are presented in Table S1. Ash content, volatile substances and the chemical characteristics of wood species are presented in Table S2, Limit values in Table S3 and PAH concentrations in Table S4.

Table S1. A schematic of the test procedure and wood species used in the tests.

Experiment	Batch 1	Batch 2	Batch 3	Batch 4	Batch 5	Batch 6

11	BirchA1	BirchB	BirchB	BirchB	BirchB	BirchB

The combustion started always with BirchA ignition batch (named BirchA1). The ignition batch consisted of 3 logs of 500 ± 20 g, 3 logs of 333 ± 20 g, and 5 logs of 100 g and two fire starter bites of approximately 10 g per bite. The subsequent batches consisted of three wood logs. Log sizes were 500 g for BirchA, 485 g for BirchB, 500 g for Alder, 515 g for Pine, 515 g for Spruce and 450 g for SpruceDry.

Italian regional restrictions: Starting from 2018, four Regions (Lombardia, Piemonte, Veneto, Emilia-Romagna) introduced the “Po basin agreement” with restrictions for domestic heating appliances and boilers up to 35 kW. In this agreement the rules are given for assignation of the number of classes (“Stars”) that each appliance will be allocated depending on results reported in the certificate of type testing, measured at nominal power output. From January 2020 only appliances with more than “4-Stars” can be installed.

The Blue Angel (German Ecolabel) for stoves (DE-UZ 212) aims to encourage innovation in the sector and promote new developments in the design of stoves for the improvement of air quality. This will be achieved using equipment to lower emissions for an efficient and controlled combustion process with a significant reduction in the emission of particulate matter and other flue gases in comparison to conventional stoves.

Table S4. Average PAH concentrations (normalized to 1 atm, 20 °C, 13% O₂ ±sd) measured from the combustion of different wood species.
