**Abstract:** The effects of low-level laser therapy (LLLT) on tumor growth are inconsistent. In this study, we investigated the effects of LLLT on melanoma tumor growth and angiogenesis. C57/BL6 mice were challenged with B16F10 melanoma cells and treated with LLLT for 5 consecutive days; untreated mice were used as controls. Tumor weight, angiogenesis, immunohistochemistry, and protein levels were compared between the treated and untreated mice. In an in vitro experiment, B16F10 cells were treated with LLLT. Proteins were extracted and subjected to Western blot analysis for analyzing signaling pathways. Compared with the findings in the untreated mice, tumor weight substantially increased in the treated mice. Both immunohistochemical and Western blot analyses revealed markedly increased levels of CD31, a biomarker of vascular differentiation, in the LLLT group. In B16F10 cells, LLLT considerably induced the phosphorylation of extracellular signal-regulated kinase (ERK), which, in turn, phosphorylated p38 mitogen-activated protein kinase (MAPK). Furthermore, LLLT induced the expression of vascular endothelial growth factor, but not hypoxia-inducible factor-1α, through the ERK/p38 MAKP signaling pathways. Our findings indicate that LLLT induces melanoma tumor growth by promoting angiogenesis. Therefore, it should be avoided in patients with melanoma.

**Keywords:** melanoma; tumor growth; angiogenesis; low-level laser therapy

# **1. Introduction**

Low-level laser therapy (LLLT), also called photobiomodulation therapy, refers to the use of light (power density <  $100 \text{ mW/cm}^2$ ; wavelength, 400–980 nm) for physiotherapy. In contrast to other medical laser procedures, this noninvasive therapy exerts its effects through photomodulation rather than through thermal mechanisms. In medicine, LLLT is used to reduce inflammation, relieve pain, accelerate wound healing, and manage softtissue injuries [\[1–](#page-10-0)[8\]](#page-11-0). However, the safety of LLLT, particularly when targeting areas with tumors, remains debatable. Several in vitro and in vivo studies have reported that LLLT can be harmful in patients receiving treatment for tumors. In urothelial carcinoma (J82) and normal urothelial (HCV29) cells, blue (410 nm), red (635 nm), and infrared (805 nm) light stimulated cell mitosis in vitro; however, the increased irradiation slightly reduced the mitotic rate in mamma adenocarcinoma (MCF7), glioblastoma (U373MG), and gingival mucosa (ZMK1) cells [\[9\]](#page-11-1). The exposure (twice) of acute myeloid leukemia (KG-1a) cells to light with an energy density of 20 J/cm<sup>2</sup> promoted cell growth [\[10\]](#page-11-2). However, LLLT with an energy density of 600 J/cm<sup>2</sup> inhibited the growth of squamous cell carcinoma (VX2) and murine colon carcinoma (CT26) cells in vitro [\[11\]](#page-11-3). These findings indicate that the mitogenic effects of light are dependent on the cell type and energy level [\[12\]](#page-11-4). At a high

dose (1050 J/cm<sup>2</sup>), LLLT (600 nm) markedly increased melanoma tumor volume, blood vessels, and cellular abnormalities compared with the findings in the control group [\[13\]](#page-11-5). In an in vivo study that was conducted using nude mice, LLLT promoted the proliferation and angiogenesis of anaplastic thyroid carcinoma cells through the protein kinase B/hypoxiainducible factor (HIF)-1 $\alpha$  pathway [\[14\]](#page-11-6). In contrast, LLLT reduced tumor growth in animal studies [\[15,](#page-11-7)[16\]](#page-11-8) and improved the survival rate in patients with cancer [\[17\]](#page-11-9).

Several mechanisms have been proposed to explain the effects of LLLT on mitochondria [\[18,](#page-11-10)[19\]](#page-11-11). It can alter cell and tissue functions, including the prevention of inflammationinduced apoptosis [\[20\]](#page-11-12), stimulation of collagen production [\[21\]](#page-11-13), promotion of DNA synthesis [\[22\]](#page-11-14), and elevation of ATP levels [\[23\]](#page-11-15). In addition, LLLT promotes cell proliferation, vascular endothelial growth factor (VEGF) expression, and angiogenesis [\[24](#page-11-16)[,25\]](#page-11-17). Angiogenesis is the growth and development of new capillaries from pre-existing vasculature, and in therapeutic angiogenesis, this phenomenon is employed to alleviate inadequate tissue perfusion [\[26\]](#page-11-18). Although LLLT is useful for treating various human diseases, its effects on cellular proliferation remain debatable; it may even induce tumor growth [\[13\]](#page-11-5).

In tumor cells, the VEGF pathway is the key regulator of angiogenesis and may include angiogenic switches [\[27\]](#page-11-19). Tumor cells release angiogenic growth factors, which promote angiogenesis; the activation of angiogenic growth factor signaling pathways, such as the VEGF/VEGF receptor pathway, mediates a network of signaling processes that attract endothelial cells toward the tumor mass, thus promoting endothelial cell growth and migration and angiogenesis [\[27\]](#page-11-19). The extracellular signal-regulated kinase (ERK)/p38 mitogen-activated protein kinase (MAPK) pathway is essential for the VEGFmediated proliferation and migration of cancer cells. In cancer cells, hypoxia upregulates the expression of many angiogenic growth factors, partly through the transcriptional activity of the HIF-1 $\alpha$  pathway [\[28](#page-11-20)[,29\]](#page-11-21).

Melanoma is the least common but the most fatal type of skin cancer [\[30\]](#page-11-22). It involves the formation of angiogenic tumors. Angiogenesis facilitates the supply of key nutrients to cancer cells, thus promoting cancer progression and metastasis [\[31,](#page-12-0)[32\]](#page-12-1). LLLT, in which the skin is exposed to laser light, may be harmful, particularly for patients with skin cancer. However, the mechanisms underlying the effects of LLLT on tumor growth and angiogenesis are unclear. Therefore, in this study, we investigated the effects of LLLT on tumor growth and angiogenesis in a mouse model of melanoma.

#### **2. Materials and Methods**

#### *2.1. Animal Model and Cell Culture*

A total of 20 male C57/BL6 mice (age, 8 weeks) were obtained from the National Laboratory Animal Center, Taipei, Taiwan. The mice were provided with standard laboratory chow and water ad libitum and maintained (in cages) under a 12 h dark/light cycle at 23 °C  $\pm$  2 °C in the animal facility of our institute. This study was approved by the Institutional Animal Care and Use Committee of China Medical University (approval number: IACUC# 2017-172). All experiments were performed in accordance with the National Institutes of Health Guide for the Care and Use of Laboratory Animals.

B16F10 melanoma cells were obtained from the Bioresource Collection and Research Center (Hsinchu, Taiwan). The cells were cultured in Dulbecco's Modified Eagle Medium (DMEM 11995065; Gibco; Thermo Fisher Scientific, Inc., Waltham, MA, USA) supplemented with 10% fetal bovine serum (Hyclone, Logan, UT, USA) and 1% penicillin/streptomycin (Thermo Fisher Scientific, Inc.) at 37 °C in a humidified atmosphere of 5%  $CO_2$ . Before the experiments, the cells were dissociated using 0.25% trypsin–ethylenediaminetetraacetic acid (EDTA; Thermo Fisher Scientific, Inc.). Cell density was evaluated by manual counting using a hemocytometer under a microscope. For animal experiments, B16F10 melanoma cells ( $5 \times 10^5$ ) were resuspended in 0.1 mL of phosphate-buffered saline and inoculated subcutaneously into the backs of C57/BL6 mice. After inoculation, the mice were randomly divided into LLLT ( $n = 10$ ) and control (no treatment;  $n = 10$ ) groups. For in vitro experi-

ments, B16F10 cells were seeded in 10-mm plates at a density of 3  $\times$  10<sup>5</sup> cells/mL and were incubated for 24 h before LLLT.

#### *2.2. Laser Irradiation*

After 14 days from the date of tumor cell implantation, the mice were anesthetized with isoflurane. Their fur was removed using a hair removal cream. The tumors were exposed to laser light (AlGaInP diode laser; AM-800; Konftec Co., Taipei, Taiwan) for 5 consecutive days. The probe of the laser device was fixed vertically 30 cm above the mice. Laser irradiation (wavelength, 660 nm) was performed at an output power of 50 mW/ $\rm cm^2$ for 10 min. The daily average of energy density was 1.91 J/cm<sup>2</sup>. We previously [\[33\]](#page-12-2) found that 1.91  $J/cm<sup>2</sup> LLT$  at 660 nm is sufficient for inducing photomodulation. The mice were anesthetized with isoflurane and euthanized though cervical dislocation 24 h after the last laser irradiation session. Tumor samples were collected for further analysis.

For in vitro experiments, B16F10 cells were irradiated using the same apparatus. The probe of the laser device was fixed vertically 30 cm above the cells inside a laminar flow hood. Laser irradiation (660 nm) was performed at an output power of 50 mW/cm $^2$  for 10 min and repeated after 24 h. The daily average of energy density was 1.91 J/cm<sup>2</sup>.

#### *2.3. Cell Proliferation Assay*

To investigate the effects of LLLT on the proliferation and viability of B16F10 cells, these cells were seeded at a density of 2  $\times$   $10^3$  cells/mL in the wells (containing 100  $\mu$ L of medium) of a 96-well plate. After 24 h incubation, the cells were exposed to LLLT for 10 min; the treatment was repeated after 24 h. Cell viability and proliferation were assessed through an MTT assay [\[34\]](#page-12-3). Briefly, after 24 h of second low level LASER irradiation, 10 µL of 5 mg/mL MTT solution was added. After incubation for 4 h at 37  $°C$ , 150 µL DMSO was added to dissolve the purple crystal sediment. The solution was transfer to a new 96-well plate and read with an ELISA reader at 540 nm. The relative cell number was estimated by absorbance value.

## *2.4. Tissue Collection*

After the mice were euthanized, the tumors were carefully excised from their backs and weighed. Tumor tissues were divided into three samples that were separately stored at −80 ◦C for protein analysis, fixed with 10% paraformaldehyde, and embedded in an optimal cutting temperature (O.T.C.) compound and snap-frozen in liquid nitrogen for cryostat sectioning, or fixed with 10% buffered-formalin for paraffin sections.

#### *2.5. Immunohistochemical Analysis*

To investigate angiogenesis, the tumor tissues were immunohistochemically stained following a previously described method [\[35\]](#page-12-4). In brief, tumor tissues that were collected from three mice of each group were soaked in 10% formalin paraformaldehyde. The paraffin-embedded tumor tissues were cut into 4-µm-thick sections. The tissue sections were deparaffinized, hydrated, boiled in Trilogy solution (Cell Marque, Rocklin, CA, USA) for 20 min, and then oxidized in  $3\%$  H<sub>2</sub>O<sub>2</sub>. Next, all the tumor sections were stained with CD31/PECAM-1 (ab28364; Abcam, Cambridge, MA, USA) and a rabbit antibody enhancer (D39; Polink-2 Plus HRP Rabbit DAB Detection Kit; GBI LABS). Immunohistochemical analysis was performed using the Polink-2 Plus HRP Rabbit DAB Detection Kit and DAB Quanto Chromogens (TA-060-QHSX and TA-002-QHCX) following the manufacturer's instructions. CD31-stained areas were observed and photographed using a light microscope (BX43; Olympus, Tokyo, Japan) and were analyzed using ImageJ (National Institutes of Health, Bethesda, MD, USA) to evaluate the density and length to blood vessels in tumor tissues.

#### *2.6. Immunofluorescence Analysis*

Immunofluorescence analysis was performed as described previously [\[33\]](#page-12-2). O.T.C. compound–embedded tissues were cut into  $7$ - $\mu$ m-thick cryostat sections. Tissue slides were fixed with ice-cold methanol and blocked with 5% normal goat serum. CD31 and collage type IV primary antibodies were used to visualize blood vessels. The secondary antibodies that were used in this experiment were goat anti-rabbit immunoglobulin G (Ig G) conjugated with Alexa Fluor 488 and donkey anti-rat IgG conjugated with Alexa Fluor 594 (Molecular Probes, Eugene, OR, USA). The tissue sections were analyzed and photographed using a fluorescence microscope (BX41M-ESD, Olympus).

## *2.7. Western Blot Analysis*

Tumor tissues were homogenized; the cells were lysed in ice-cold buffer (pH 7.5; composition: 25 mM HEPES, 300 mM NaCl, 1.5 mM MgCl<sub>2</sub>, 0.2 mM EDTA, 0.1% Triton X-100, 20 mM β-glycerophosphate, 0.1 mM sodium orthovanadate, 0.5 mM dithiothreitol, 100 g/mL phenylmethylsulfonyl fluoride, and  $2$  g/mL leupeptin). The protein concentration was measured using the Bradford method (Bio-Rad Laboratories, Hercules, CA, USA). Approximately 40 µg of protein was separated through electrophoresis on a 10% sodium dodecyl sulfate–polyacrylamide gel. Then, the protein bands were transferred onto a polyvinylidene fluoride membrane (pore size, 0.45 µm; Millipore, Bedford, MA, USA) using a transfer apparatus (Bio-Rad Laboratories). Next, the membrane was blocked with 5% nonfat evaporated milk powder dissolved in Tris-buffered saline–Tween 20 buffer (pH 7.6; 25 mM Tris-HCl, 150 mM NaCl, and 20, 0.1% Tween) and was incubated with primary antibodies against CD31, HIF-1 $\alpha$ , VEGF, GAPDH, phospho-p38, p38, phospho-ERK, ERK, and β-actin. Table [1](#page-3-0) lists the sources of these primary antibodies. After probing with horseradish peroxidase–conjugated secondary antibodies, the protein bands were visualized using an enhanced chemiluminescence reagent (Merck Millipore, Bedford) and analyzed using ImageJ.

<span id="page-3-0"></span>**Table 1.** Antibodies for Western blot analysis.

### *2.8. Statistical Analysis*

The data are presented as the mean  $\pm$  standard error. Statistical analyses were performed using SPSS Statistics (version 20.0; IBM Corporation, Armonk, NY, USA). Betweengroup comparisons were performed using a nonparametric Mann–Whitney U test. *p* < 0.05 indicated statistical significance.

## **3. Results**

# *3.1. LLLT Enhanced Tumor Progression In Vivo, but Not Cell Proliferation In Vitro*

To investigate the effects of LLLT on tumor growth, we assessed the progression of B16F10 melanoma in vivo. Figure [1A](#page-4-0) depicts treated and untreated tumors on Days 1 and 5. Changes in the tumor area at Day 5 from Day 1, and tumor weight at Day 5 are presented using bar graphs (Figure [1B](#page-4-0),C). No prominent differences were noted between the treatment and control groups in terms of changes in the tumor area  $(238.8 \pm 42.13$  and  $204.3 \pm 16.56\%)$ . By contrast, the tumor weight markedly increased in the treatment group compared with that in the control group (0.2703  $\pm$  0.1628 and 0.7639  $\pm$  0.2373 g). The actual tumor size

cannot be measured simply using photographs because the three-dimensional structure of tumors cannot be captured in photographs. To further investigate the effects of LLLT on cell proliferation of B16F10 in vitro, MTT cell viability assays were used. As shown in Figure [1D](#page-4-0), LLLT did not enhance the in vitro proliferation of B16F10 cells.

<span id="page-4-0"></span>

#### *3.5. LLLT Induced the Expression of VEGF, but Not HIF-1α, through ERK Signaling 3.5. LLLT Induced the Expression of VEGF, but Not HIF-1α, through ERK Signaling*

LLLT did not induce prominent changes in the expression levels of HIF-1α and VEGF. LLLT did not induce prominent changes in the expression levels of HIF-1 $\alpha$  and<br>MESE Western bloc analysis. The expression levels of HIF-1 $\alpha$  and The expression vertex of Western blot VEGF. We suspected that non-tumor tissues interfered with the results of Western blot vitros<sup>1</sup> analysis. Thus, we further evaluated the expression levels of HIF-1 $\alpha$  and VEGF in vitro. To understand the roles of ERK and p38 MAPK in the LLLT-mediated induction of HIF-1 $\alpha$ and VEGF expression, B16F10 melanoma cells were pretreated with U0126 and SB203580. The expression levels of HIF-1 $\alpha$  and VEGF were measured through Western blot analysis. LLLT increased the expression levels of HIF-1α and VEGF in B16F10 melanoma cells (Figure [5A](#page-8-0),B). Compared with the findings that were noted in the control group, HIF-1 $\alpha$ expression was upregulated in the treatment group; pretreatment with U0126 or SB203580 did not inhibit this effect. By contrast, pretreatment with U0216 and SB203580 markedly reduced LLLT-induced VEGF expression. These findings indicate that LLLT induces the expression of VEGF, but not HIF-1 $\alpha$ , through the ERK/p38 MAPK pathway.

## **4. Discussion 4. Discussion**

In the present study, LLLT did not enhance B16F10 cell proliferation in vitro but increased B16F10 tumor growth through its angiogenic effects in vivo. This therapy induced the phosphorylation of ERK and p38 MAPK and increased the expression levels of VEGF in B16F10 cells. It further induced CD31 expression and enhanced vascularization in subcutaneous tumors. Taken together, our findings suggest that LLLT accelerates tumor progression by promoting angiogenesis and modulating the ERK/p38 MAPK/VEGF signaling pathway (Figure [6\)](#page-8-1).

<span id="page-8-1"></span>

**Figure 6.**  $\frac{P}{P}$   $\frac{P}{P}$  esis. The skin is directly exposed to laser light during LLLT. Therefore, investigating the effect of LLLT on melanoma is crucial. Although LLLT is useful for wound healing, ischemia  $\sigma$ Melanoma is a highly invasive skin cancer that metastasizes at the early stages [\[32\]](#page-12-1). treatment, and antitumor outcomes, the mitogenic potential of LLLT may increase tumor growth [\[36\]](#page-12-5). LLLT at a dose of 150 J/cm<sup>2</sup> exerts no strong effect on melanoma tumor size, but a higher dose (1050 J/cm<sup>2</sup>) can promote tumor growth with distinct histological features in vivo; this finding indicates that the LLLT dosage differentially affects tumor cell proliferation [\[13\]](#page-11-5). In cultured B16F10, our results also showed LLLT did not stimulate cell proliferation, however, we observed that LLLT at a low dose of 1.91 J/cm<sup>2</sup> upregulated the expression of angiogenesis-related signaling molecules and increased the weight of B16F10 melanoma tumors, which implies that LLLT accelerates the progression and aggressiveness of melanoma through angiogenesis. Frigo et al. also used B16F10 as a melanoma model; however, they inoculated B16F10 cells into BALB/c mice instead of C57BL/6 mice, which are the syngeneic model of B16F10 melanoma and highly susceptible to metastasis. As C57BL/6, but not BALB/c, mice are an immunocompetent syngeneic model for B16F10 melanoma [\[37\]](#page-12-6), the tumorigenic effects of low-dose LLLT elicited different immune responses in our study. The inhibitory effects that were reported by Frigo et al. might have resulted from the LLLT-induced immune response against melanoma. However, human melanoma may exhibit high immunogenicity through immune evasion [\[38\]](#page-12-7). Further studies are needed to clarify the effects of LLLT on immune responses.

Several mechanisms may mediate the effects of LLLT on angiogenesis. LLLT induces VEGF expression in various cell and animal models [\[25,](#page-11-17)[39,](#page-12-8)[40\]](#page-12-9). Low-level laser light enhances ERK phosphorylation and VEGF secretion in human granulosa cells [\[41\]](#page-12-10). VEGF is a major mediator of angiogenesis by binding with receptor-2 (Flk-1/KDR) and activating the ERK and HIF-1 $\alpha$  signaling pathways [\[42–](#page-12-11)[44\]](#page-12-12). We previously demonstrated that LLLT strongly induces the phosphorylation of VEGF, HIF-1 $\alpha$ , and ERK [\[33\]](#page-12-2). The expression of both VEGF and ERK is an upstream signal to that of CD31, which is involved in vasculogenesis and angiogenesis [\[45](#page-12-13)[,46\]](#page-12-14). Accordingly, LLLT partly promotes angiogenesis by increasing the expression levels of relevant signaling molecules that affect development, reproduction, and wound repair. Angiogenesis is pivotal to cancer development, specifically for tumor growth, progression, and metastasis [\[47\]](#page-12-15). The surface of endothelial cells exhibits high levels of CD31, which is a biomarker of vascular differentiation in malignant tissues. CD31 is also a well-known inducer of angiogenesis and is specifically involved in cell–cell communication, which is essential for the maturation of blood endothelial cells [\[46,](#page-12-14)[48\]](#page-12-16). Tumors with high CD31 positivity and VEGF positivity indicate early-stage cancer; a higher number of blood vessels implies a higher rate of relapse [\[46\]](#page-12-14). In the present study, we found that LLLT increased CD31 levels in tumors, whereas it increased VEGF levels through the ERK/p38 MAPK pathway in B16F10 melanoma cells. Taken together, the results suggest that LLLT accelerates tumor progression by enhancing VEGF expression and thus tumor angiogenesis.

Although most studies have reported similar effects of LLLT on angiogenesis, several studies have indicated the differential effects of LLLT on tumor growth. Ottaviani et al. demonstrated that three LLLT protocols (660 nm, 50 mW/cm<sup>2</sup>, and 3 J/cm<sup>2</sup>; 800 nm,  $200$  mW/cm<sup>2</sup>, and 6 J/cm<sup>2</sup>; and 970 nm, 200 mW/cm<sup>2</sup>, and 6 J/cm<sup>2</sup>; once daily for 4 days) increased the density of  $\alpha$ -smooth muscle actin–positive vessels in tumor samples but decelerated tumor progression [\[15\]](#page-11-7). In the present study, we also used the wavelength of 660 nm; however, the fluence is lower than that in the aforementioned study because of a relatively large beam diameter. Studies that were conducted by Da Xing et al. in China have revealed that low-power laser irradiation with high fluence can restrict tumor growth through the photoinactivation of respiratory chain oxidase [\[49,](#page-12-17)[50\]](#page-12-18). The inconsistency in these results might be because of the differences in fluence. In addition, different wavelengths, power, optical properties, and cell types may lead to different responses to photochemical stimulation [\[10,](#page-11-2)[51\]](#page-12-19).

Our study has some limitations. First, the higher expression level of CD31 might not be a good biomarker to tumor progression. Langenkamp and colleagues found the vascular morphology shifts from small vessels without lumen in small B16F10 melanoma to vessels with lager lumen in intermediate/large tumors, and we found similar changes

in LASER-irradiated tumors. However, they reported that there is no difference of CD31 mRNA expression in different stages of melanoma [\[52\]](#page-12-20). Previous studies have also reported that CD31 is only suitable as a prognostic biomarker for small, but not late stage, laryngeal squamous cell carcinoma [\[46\]](#page-12-14). Thus, the LLLT-induced higher protein expression of CD31 in our model might only happen in the early stage of tumor formation. Second, the in vivo and in vitro study findings were inconsistent. For instance, although B16F10 cells and melanoma tumors were irradiated with the same dose, LLLT markedly upregulated the expression of VEGF and HIF-1 $\alpha$  in B16F10 cells, but not in melanoma tissues. Whether the degrees of LLLT-mediated photomodulation are similar between in vivo and in vitro experiments must be investigated further. Tumor microenvironments vary across cancer types and are crucial for tumor growth and immune evasion. The differences between in vitro and in vivo findings imply that the mitogenic effects of LLLT on B16F10 cells are not 100% similar to its mitogenic effects on patients with melanoma. Further studies are needed to validate our findings.

## **5. Conclusions**

In the present study, LLLT (wavelength, 660 nm; power density, 50 mW/cm<sup>2</sup>; energy density, 1.91 J/cm<sup>2</sup>) increased tumor weight and promoted angiogenesis. Distinct histological features were observed. Thus, LLLT may aggravate melanoma, thereby worsening disease prognosis. Our in vitro and in vivo study findings indicate that LLLT is unsafe for patients with skin cancer, particularly those with melanoma. Therefore, clinicians and physiotherapists must avoid this therapy in patients with skin cancer.

**Author Contributions:** All authors contributed to study conception and design. Material preparation, data collection, and data analyses were performed by Y.-J.C. and Y.-Y.L. The first draft of the manuscript was written by Y.-J.C. and revised by S.-Y.L. All authors have read and agreed to the published version of the manuscript.

**Funding:** This study was supported by the Taiwanese Ministry of Science and Technology (grant number: MOST 111-2410-H-039-004-), China Medical University hospital (grant number: DMR-110- 172), and China Medical University (grant number: CMU111-MF-89).

**Institutional Review Board Statement:** The protocols for animal experiments were reviewed and approved by the Institutional Animal Care and Use Committee at China Medical University (approval number: IACUC# 2017-172). All experiments were performed in accordance with the ARRIVE guidelines [\(https://arriveguidelines.org,](https://arriveguidelines.org) accessed on 13 January 2023).

**Informed Consent Statement:** Not applicable.

**Data Availability Statement:** The datasets generated and analyzed in this study are available from the corresponding author upon reasonable request.

**Acknowledgments:** This manuscript was edited by Wallace Academic Editing.

**Conflicts of Interest:** The authors declare no conflict of interest.
