

Supplemental Table S1: Mean (\pm SE) percentage of fruitlets bagged at petal fall and assessed in August of each year (2016, 2018 and 2019) from two blocks of apple trees located at Kentville Research and Development Centre in Nova Scotia which were healthy, showed damage from other insects ('Other Damage'), failed to develop, had *Hoplocampa testudinea* damage and dropped from the tree ('EAS drop') or remained attached to the tree ('EAS tree') and combined damage ('EAS total').

Year	Block	Cultivar	Mean (\pm SE) percentage of fruitlets (%)				
			Healthy	Other Damage	Failed to Develop	EAS drop	EAS tree

Supplemental Figure S1: Mean (\pm SE) change in A) percent soluble solids and B) acidity of fruitlets during fruitlet development from 10 to 20 mm and from 20 to 30 mm in size. Fruitlets collected from 15 cultivars in two blocks located at the Kentville Research and Development Centre, Nova Scotia over 2017-2019. Note: “Delblush” cultivar was not included in this analysis due to lack of available fruitlets over all years and “S47-23-100” did not have sufficient fruitlets in 2017.

Supplemental Figure S2: (A) Mean (\pm SE) force required to break the skin of fruitlets collected when 20 and 30 mm in size and (B) change in force during development from 15 cultivars in 2 blocks located at the Kentville Research and Development Centre in Nova Scotia over 3 years (2017-2019).
