S.1. Likert's five-point spectrum, codes, and definitions

Table S1. Likert's five-point spectrum, codes, and definitions

Numeric value	Response spectrum	Code	Definition
5	Strongly Agree	SA	Very Agree/Very High
4	Agree	A	Agree/High
3	Neutral	N	No Opinion/Abstain
2	Disagree	D	Disagree/Low
1	Strongly Disagree	SD	Very Disagree/Very Low

S.2. Boruta method

Boruta is a variable selection model that aims to find all relevant variables in a dataset. It is based on the idea of comparing the importance of original variables with randomly generated shadow variables [1]. The shadow variables are copies of the original variables with shuffled values. Boruta uses any classifier such as decision trees or support vector machines [2]. In our study, we use a DT classifier to assign an importance score to each variable and then compare the scores of original and shadow variables. If an original variable has a higher score than the maximum score of any shadow variable, it is considered relevant and confirmed. If an original variable has a lower score than the minimum score of any shadow variable, it is considered irrelevant and rejected. Calculating the accuracy of the model preserves the questions that improve the model and candidates to discard the questions those do not improve the model with a confidence point of 0.95 [1]. If an original variable has a score between the minimum and maximum scores of any shadow variables, it is considered tentative and needs more iterations to decide [1], [2]. In Table S2, questions that were removed by the Boruta method from the decision tree model are indicated.

Table S2. Confirmed questions based on the Boruta method using the DT model with a ratio of 30% test to 70% learning for train data.

S.3. Mutual Information method (Maximum Relevance Minimum Redundancy)

In the realm of variable selection, mutual information plays a pivotal role by quantifying the relationship between two variables – the dataset's variables and the target variable for prediction. MI measures the amount of information a variable provides about the target variable, aiding in identifying influential variables. The goal in variable selection is to maximize MI by selecting informative variables while minimizing redundancy. This process enhances model performance and reduces complexity. The optimization hinges on both elevating mutual information among chosen variables and ensuring their uniqueness. Achieving this balance involves strategic selection and optimization under constraints, ultimately bolstering the predictive power and effectiveness of the chosen variables.

Mutual information $I(X; Y)$ (in Eq S1) is defined as the difference between the joint entropy of the two variables (X and Y) and the conditional entropy of one variable given the other. The entropy terms, $H(X)$ and $H(Y)$ (in Eq S2), represent the amount of uncertainty in variables X and Y , respectively. The MI formula, $I(X; Y) = H(X) - H(Y|X)$, captures the shared information between X and Y . It can be computed through the summation of probabilities of their joint distribution and conditional probabilities.

$$I(X; Y) = H(X) - H(X|Y) = H(X) - H(Y|X) = \sum_{x,y} p(x,y) \log \frac{p(x,y)}{p(x)p(y)} \quad (\text{Eq S1. Mutual information})$$

Where the $H(X; Y)$ is the entropy and the function $I(X; Y)$ computes the extent of required information.

$$H(X; Y) = - \sum_{x \in X} \sum_{y \in Y} p(x,y) \log p(X; Y)$$

$$H(Y|X) = - \sum_{x \in X} \sum_{y \in Y} p(x, y) \log p(y|x)$$

(Eq S2. Commands pertaining to mutual information)

Mathematically, mutual information is calculated as the difference between the joint entropy of variables X and Y , representing variables and the target variable respectively, and the conditional entropy of one variable given the other. This captures shared information between the variables and guides variable ranking. Higher mutual information values indicate more relevant variables with greater predictive potential.

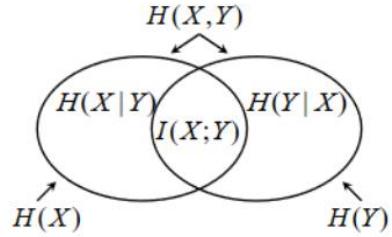

Figure S1. How the $I(X;Y)$ obtain the information by mutual information method [3].

In Figure S1, utilizing the computation of $I(X;Y)$, while considering the set S as the set of variables, the maximal correlation (Eq S3) and minimal redundancy (Eq S4) are derived. This entails optimizing for the utmost correlation. The MRMR (Maximum Relevance Minimum Redundancy) as a part of mutual information method is a variable selection technique that aims to choose variables that have high relevance to the target variable while minimizing redundancy among selected variables [3]. The Maximum Relevance Minimum Redundancy model aims to identify a subset of variables that have high relevance to the target variable while minimizing redundancy among the selected variables. The values of $H(x)$ and $I(x)$ respectively represent the relevance of a variable to the target variable, and redundancy between variables which was calculated with a significance point of $\alpha=0.05$. The negative scores of MRMR are the candidate

for removing from the model (highlighted in yellow). Results are presented in Table S3. In this method, most of non-Likert type multi-choice questions, pertain to pedagogical methods such as the flipped class and the name of the learning management system, focusing on the educational management environment and classroom monitoring selected [3].

Maximization of correlation (V):

$$\max V_I;$$

$$V_i = \frac{1}{|S|} \sum_{i \in S} I(h, i)$$

(Eq S3. Maximization of correlation)

Minimal redundancy (W):

$$\max W_I;$$

$$W_i = \frac{1}{|S|^2} \sum_{i,j \in S} I(h, i)$$

(Eq S4. Minimal redundancy)

Table S3. Score of questions by MRMR method.

S.4. Recursive Feature Elimination

The Recursive Feature Elimination (RFE) process involved initially considering all variables and subsequently removing variables one by one until the last variable was eliminated, while assessing the changes in accuracy. Recursive Feature Elimination and Boruta are two commonly utilized wrapper methods [4]. Recursive Feature Elimination is an iterative variable selection technique that begins with all variables and progressively eliminates the least significant ones. It achieves this by training the model with the full set of variables, ranking them based on their importance, and subsequently removing the least important variables [4]. Given a dataset with n instances and p variables, the goal of RFE is to iteratively select a subset of variables S of size k that minimizes a chosen performance metric J while reducing k from p to a predefined stopping criterion:

$$S^* = \arg \min_S \{J(S)\} \quad (\text{Eq 5. } S^* \text{ as the selected subset of variable } S)$$

Where $S \subset \{1, 2, \dots, p\}$ and $|S| = k$. At each iteration, the least important variable according to a certain criterion is removed, and the process is repeated recursively until the

stopping criterion is met. The choice of performance metric J and the method for ranking variable importance may vary based on the specific problem and model being used. RFE procedure resulted in a list of variables, ranging from the first output to the final output variable, at a significance point of $\alpha=0.05$. The RFE will be on train data and with $k=10$ for students (I2, I4, I6) and $k=5$ for instructors (H2, H4, H6) and random forest with 500 trees (test 30%, train 70%).

Table S4 indicates the results of the RFE method of variable selection for different values of k (number of variables to select) on a dataset. The table indicates the accuracy, kappa, accuracy standard deviation, kappa standard deviation, and whether the variable was selected for each value of k. The optimal number of variables is indicated by the star (*) in the last row and this number of items is the best first number of items to be added and do not meaningfully decrease the accuracy. However, sometimes item number 4 or 7 are the items that indicate the drop-down of accuracy but because we have to reject most of the items, we will jump to the next item that drop happening there. The accuracy and kappa values are measures of the performance of the model with the selected variables. The accuracy is the proportion of correctly classified instances, while the kappa is a measure of agreement between the predicted and actual classes that takes into account the possibility of agreement by chance. The accuracy and kappa standard deviations indicate the variability of the performance estimates across different cross-validation folds. The RFE method of variable selection works by recursively eliminating the least important variables until the desired number of variables is reached. The variables are ranked by their importance based on the model's coefficients or variable importance, and the least important variables are eliminated in each iteration. The optimal number of variables is determined by running cross-validation on the top of the RFE class. As the data inaccuracy in some of the response variables

get the variables with less than 10 questions and the accuracy didn't change more than 0.1 and again the accuracy recovered itself, so we consider the further number of variables for subsets.

Table S4. Ranking of number of best subsets with k=5 (students) and k=10 (instructors) of RF for RFE method as variable selection

S.5. chi-square test for variable selection

The chi-square test has been employed in the variable selection section, essentially examining the interdependence between each pair of variables and between each predictor variable and the response variable. Moreover, the mutual information tool leverages the measurement of the proximity or resemblance of the joint distribution function of two variables or their marginal functions [5], [6]. The following delineates the methodology of this approach, assuming that X and Y are multivariate random variables, and $p(x; y)$ represents the joint probability density function:

$$I(X; Y) = \int_X \int_Y p(x, y) \cdot \log \frac{p(x, y)}{p(x)p(y)} dx dy \quad (\textbf{Eq S6. Joint probability density function})$$

A value of zero in the mutual information measure $I(X; Y)$ signifies that the two variables are completely unrelated or independent. Conversely, leveraging principles of linear algebra and

operational research, it is feasible to obtain a suitable ranking of k variables using the following objective function:

$$\tilde{S} = \arg \max_S I(X_S; y),$$

$$s.t. |S| = k,$$

(Eq S7. Joint probability density function)

To use the chi-square test for variable selection, we need to compute the chi-square statistic for each variable with respect to the target question and compare it with a critical value or a p-value based on a significance point. We can then select only those variables that have chi-square statistics above the critical value or p-value below the significance point [5], [6]. It should be noted that solving this problem, in the context of operational research models and methods, is approached progressively, recursively, and incrementally. Each approach encompasses distinct characteristics; for instance, in the forward-looking solution, this objective function is employed by assuming the maximization of the divergence between frequencies and the relevance function $I(X; Y)$ [5–6]. For variable selection using the chi-square test, the chi-square statistic is computed for each variable in relation to the target question and compared to a critical value or p-value determined by the chosen significance point. Variables with chi-square statistics exceeding the critical value or p-values below the significance point are selected [7]. As the chi-square test as the filter method do not have the direct method for selecting threshold, we had to use the k-fold of cross validation of wrapper method specifically the RFE method. As the RFE clear the best number of variables by cross validation, we will use that number as the threshold of chi-square test.

Table S5. Results of Chi-squared ranking by considering the order of question from k fold of cross validation by RFE method.

S.6. Majority Voting in variable selection

Table S6 indicates the variables that each of the chi-square, MRMR, Boruta, and RFE methods selected (sections A.2 to A.6; Tables A2 to A5) and describes the situation of each variable and the reason for its selection. These variables were used for ML models as input. As the REF considers the population of first best variables that enter to the ML and Chi-square consider the variables that have less relation to the response variable and do not have a general rule to exclude the items based on P-value, we just used the first best variables of Chi-square as one result in Table S6.

Table S6. Rejected and confirmed questions based on the variable selection methods and by the data frame that involved.

#	code	Chi-squared & RFE	MRM R	Boruta	>2: reject <2: confirm	#	code	Chi-squared & RFE	MRM R	Boruta	>2: reject <2: confirm

S.7. Chronic correlation

This approach has been employed to compute correlation in the "4-3-2- Correlation" section. In summary, consider Z1 and Z2 as two ordinal questions with categories 1m and m2, respectively. Their distribution in the sample is presented through a provided probability table.

n₁₁	...	n_{1m2}
n₂₁	...	n_{2m2}
.
.
n_{m1}	...	n_{m1m2}

The variables Z_1^* and Z_2^* can be regarded as those for which their combined distribution follows a bivariate normal distribution exhibiting correlated behavior. Multivariate correlation arises from the various states of the bivariate (or multivariate) normal distribution $N(0,0,1,1,\rho)$

$$P[X = i, Y = j] = p_{ij} = \int_{a_{i-1}}^{a_i} \int_{b_{j-1}}^{b_j} \frac{1}{2\pi\sqrt{1-\rho^2}} \exp^{-\frac{1}{2(1-\rho^2)}(x^2 - 2xy\rho + y^2)} dx dy$$

(Eq S8. Chronic correlation)

Whereby an objective function can be defined as follows:

$$\ln L = \sum_{i=1}^{m1} \sum_{j=1}^{m2} n_{ij} \log p_{ij}$$

(Eq S9. Objective function of Chronic correlation)

However, in this method, it is necessary to assume the normality of the two variables prior to calculating the tested correlation, and given such a presumption violation, this correlation holds relatively robustly. This approach is employed for continuous values, yet it should be noted that it can also encompass discrete values.

S.8. Heterotrait-Monotrait

The Heterotrait-Monotrait (HTMT) correlation ratio is an approach to examine the extent to which latent constructs are independent of each other, as per the formula provided in equation 6 of Henseler, Ringle, and Sarstedt [8]. Tables A6 and A7 indicate the HTMT values for all subscales of both surveys. The highest HTMT value observed for instructors is 0.6 and for students

0.532. By ensuring that the HTMT values remained below the threshold of 0.9 for both instructors and students, we confirmed sufficient distinction between the any two subscales in both surveys. The results confirm the appropriateness of correlations between attributes of different subscales and indicate the extent the subscales differ from each other assessed [9].

Table S8. Heterotrait-Monotrait ratio output for instructors (points of significance)

$\alpha=0.005$, N=140	Theory and practice	Motivation	Pedagogy	Knowledge, Insight, and Skill	Working-Life orientation	Quality of Assessment and ICT
Theory and practice						
Motivation	0.427					
Pedagogy	0.425	0.423				
Knowledge, Insight, and Skills	0.612	0.518	0.510			
Working-Life orientation	0.512	0.418	0.319	0.455		
Quality of Assessment and ICT	0.415	0.402	0.326	0.517	0.316	

Table S9. Heterotrait-Monotrait ratio output for students (points of significance)

$\alpha=0.005$, N=379	Theory and practice	Motivation	Pedagogy	Knowledge, Insight, and Skill	Working-Life orientation	Quality of Assessment and ICT
Theory and practice						
Motivation	0.413					
Pedagogy	0.446	0.53				
Knowledge, Insight, and Skills	0.532	0.518	0.538			
Working-Life orientation	0.472	0.401	0.419	0.385		
Quality of Assessment and ICT	0.365	0.302	0.416	0.451	0.326	

S.9. Shorter survey

The study aimed to identify the most important questions for predicting preferences among the 55 questions included in the surveys. Table S8 highlighted the instructors' and students' surveys as the most crucial. These surveys encompassed all the subscales and were applicable to both students and instructors. The study further extracted 12 and 11 specific questions from these surveys for instructors and students by the MDI more than 0.86. This shortened survey allows for the collection of more extensive data in future research endeavors. Additionally, the selection of

questions in this shortened survey ensures a balanced distribution across the six subscales. The accuracy of the shortened survey was evaluated in Table S10, which reports the change in accuracy when considering the results from the five-point and 3-point Likert scales. The preference prediction was initially conducted using the 12 selected questions, employing classification methods as outlined in section A.4 – A.7. The Table S10 presents the difference between the accuracy obtained from the shortened survey and the accuracy values derived from the original survey. The accuracy reductions were lowest for the random forest method, indicating that utilizing the shortened survey with its 12 main questions, despite some reduction in prediction accuracy, enables the gathering of more extensive statistical data.

Table S10. Best 12 questions of instructors and 11 questions of students.

Question	Instructors	Students
Usability and perception of alternative laboratory tools	F4	F5
Motivation in TEL environment is higher than traditional environment	B2	B4
Capability of TEL tools in transferring hard and soft skills	C4	C2
Comparison of active learning methods in TEL environment with traditional teaching methods	E4	E2
Evaluation in TEL environment and its quality compared to traditional method	G1	G3
Ability to teach real-world problem solving	B4	B2
Classroom management strategy for adaptation in TEL	E2	E5
Flexibility in teaching and learning in TEL compared to face-to-face teaching	D2	D1
The extent to which course delivery becomes practical in TEL compared to face-to-face teaching	A1	A4
Willingness to change role and become an active actor in TEL	B1	B3
Monitoring educational progress and understanding learning from people during class time in TEL	E5	-
The ability to create research and interactive communication outside the classroom in TEL	F3	F7

S.10. ML in detail

S.15. Mean Decrease in Impurity

The Mean Decrease in Impurity (MDI) is a methodology used in decision tree-based models, such as Random Forest, to assess the importance of individual variables in making accurate predictions. It quantifies the contribution of each variable to the overall reduction in impurity, typically measured by Gini impurity or entropy, achieved through the splitting of nodes in the decision tree. The MDI is computed by averaging the impurity decrease across all decision tree nodes where a specific variable is utilized for splitting. Mathematically, for a given variable j , the MDI can be expressed as:

$$MDI(j) = \frac{1}{N_{nodes}} \sum_{\text{nodes using feature } j} (Impurity \text{ before split} - Impurity \text{ after split})$$

(Eq S10. MDI formulation [10], [11])

Where N_{nodes} is the total number of nodes that utilize variable j for splitting, and the impurity decrease is calculated as the difference between the impurity of the node before the split

and the weighted sum of impurities of resulting child nodes after the split. In our data set, Specifically, for each variable j , the MDI is calculated by averaging the impurity decrease across all nodes where variable j is used for splitting. Once the MDI values are computed for all variables (questions), they can be used to rank the importance of each variable in predicting the target variable. Higher MDI values indicate that a variable contributes more to reducing impurity, which signifies its importance in classification. To determine the importance of each subscale, aggregate the MDI values of the questions belonging to each subscale. Summing or averaging the MDI values of questions within a subscale provides an estimate of the subscale's overall importance in the classification task. Subscales with higher aggregated MDI values are considered more influential in making accurate predictions [10], [11]. We designed the Table S9 by analyzing the Figures A2 to A10.

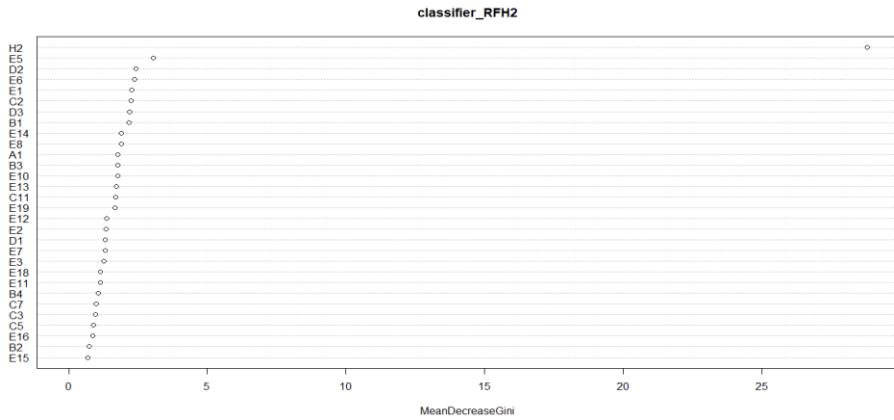

Figure S2. Variable Importance in Random Forest for H2 (Instructors) within the five-level Likert spectrum

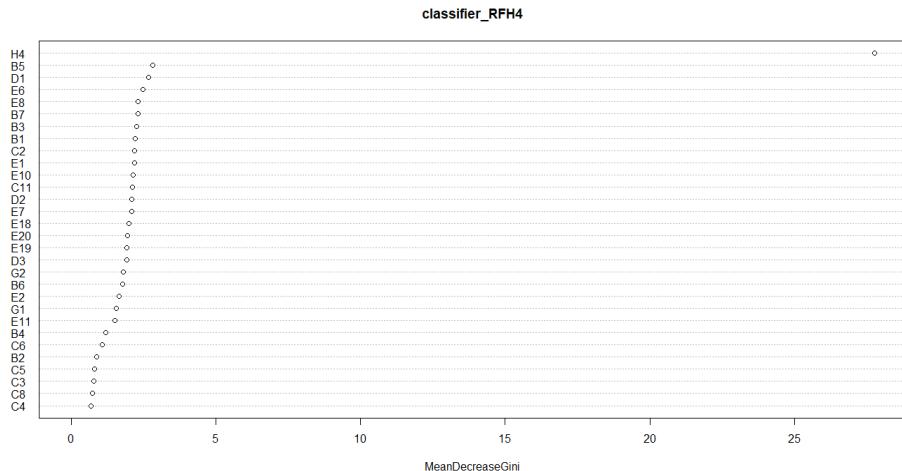

Figure S3. Variable Importance in Random Forest for H4 (Instructors) within the five-level Likert spectrum

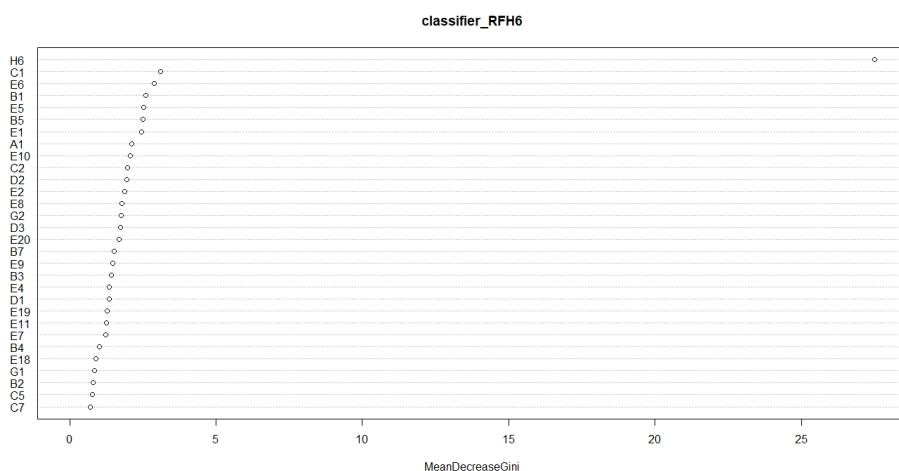

Figure S4. Variable Importance in Random Forest for H6 (Instructors) within the five-level Likert spectrum

Utilizing Tables A18 to A20, within the 5-point Likert spectrum, the Random Forest method was employed on the test data for survey response variables of Students, resulting in the accuracy of the models. These tables have been succinctly summarized in Tables A19.

S.16. Software and code

R is an open-source programming language that, following installation and incorporation of various libraries and packages, can execute a diverse range of pre-written and customized commands. An appended list of these libraries is provided herein. It is noteworthy that the version of R Studio in use is the latest available version 4.1.3, which is freely accessible to the public [8].

Table S20. R packages and their citations

Name	Library or function with citation	Name	Library or function with citation

- R codes for Variable selection [Link](#)
- Excel of full ML results [Link](#)

Table S21. Survey of students and instructors (translated from Farsi (Persian) to English)

	Code	Question of students	Subscale
1	A1	Implementing important actions and practical experiments for engineers is possible in an online learning environment.	Theory and practice
2	A2	The university should shift its focus from theory to dedicated practical applications.	
3	A3	Online learning assists me in connecting theory and application effectively.	
4	A4	Instructional videos of experiments, research articles, and empirical data provided for analysis and interpretation can be a good substitute for practical actions in the online learning environment.	
5	B1	Online learning has transformed my role as a student in class, making me more engaged and active rather than just a passive receiver of knowledge.	Motivation
6	B2	My motivation for education/studying/participating in online learning environments is lower compared to traditional in-person classes.	
7	B3	Online education increases my independence and flexibility in learning, allowing me greater control over my learning process.	
8	B4	In an online learning environment, a student can track their progress effectively.	
9	C1	I believe technology-based learning is effective in providing practical skills.	Knowledge, Insight, and Skill
10	C2	I believe technology-based learning is effective in providing soft skills.	
11	C3	I prefer working independently and focusing on individual activities in the online learning environment.	
12	C4	Online learning is suitable for learning any type of skill, whether practical or Theoretical.	
13	C5	In the online learning environment, emphasis should be placed on teaching problem-solving skills relevant to real-life situations.	
14	C6	In my opinion, students acquire knowledge, insight, and skills better in their field through collaborative online learning.	
15	C7	Engaging in group activities and projects in the online learning environment is easier than in traditional in-person classes.	
16	C8	The online learning environment helps students acquire problem-solving skills transferable to various contexts and platforms.	
17	C9	I understand the difference between a virtual lab and a remote lab.	
18	C10	I think using online methods based on virtual labs for learning hard skills is suitable.	
19	C11	I think using online methods based on remote labs for learning hard skills is suitable.	
20	C12	I think using online methods based on virtual labs for learning soft skills is suitable.	
21	C13	I believe the essential skills for successful participation in online courses, such as time management and effective communication (individual and content-based), are necessary.	Working-life orientation
22	D1	I believe universities should provide more opportunities for students to engage in projects in industrial environments.	
23	D2	I am satisfied with the university's support (technical, mental, attitudinal, etc.) in preparing students for the job market.	
24	D3	I believe tasks and activities in technology-based courses should, to the extent possible, be based on real workplace issues.	
25	D4	I believe technology-based learning should focus more on teaching problem-solving skills relevant to real-life situations.	Pedagogy
26	E1	The average level of proficiency of our professors in using technology-based learning is appropriate.	

27	E2	The teaching methods and strategies used by professors in online classes lead to better and deeper learning.	
28	E3	Professors in online classes clearly communicate learning objectives, expectations, participation rules, teaching methods, activities, and assessment methods from the beginning of the course.	
29	E4	Assessment in the online learning environment is reliable.	
30	E5	Active learning methods are more effectively implemented in the online learning environment.	
31	E6	The content and resources in online courses are of high quality and contribute to better and deeper learning.	
32	E7	Professors provide timely and comprehensive feedback in the online learning environment.	
33	E8	Which of the following activities do your professors use more in the online learning environment?	
34	E9	In your opinion, which of the following activities is more effective for implementation in the online learning environment?	
35	F1	Have you experienced using a Learning Management System (LMS)?	Quality of assessment and ICT
36	F2	I regularly follow the course through the Learning Management System (LMS).	
37	F3	I regularly attend live sessions of the course through the Learning Management System (LMS).	
38	F4	The audio and visual quality of live (synchronous) online learning sessions is at a high level (independent of internet speed and bandwidth).	
39	F5	Overall, working with the Learning Management System is easy and user-friendly.	
40	G1	Professors are knowledgeable about appropriate student assessment methods in the online learning environment.	
41	G2	Professors use various innovative methods (projects, oral questions, peer assessment, e-portfolios, etc.) for assessment in the online learning environment.	
42	G3	In my opinion, when professors conduct assessments periodically throughout the term, not just once at the end, learning is enhanced.	
43	G4	In my opinion, providing timely feedback on the learning process, activities, assignments, and exams by professors improves learning.	
44	G5	Professors use modern technologies like simulations in the online environment.	
45	G6	The use of modern elements and technologies in the online learning environment has increased my motivation and excitement for learning.	Response variables
46	G7	Assigned activities by professors in the online environment, compared to traditional classes, are more effective in enhancing the depth of learning.	
47	G8	Online learning boosts my motivation to actively participate in class.	
48	I2	I feel satisfied using technology-based learning in Theoretical classes.	
49	I4	I am satisfied using technology-based learning in practical classes (labs, workshops).	
50	I6	I feel satisfied using technology-based learning in Theoretical-practical classes.	
	Question Code	Question of instructors	Subscale
1	A1	I emphasize Theoretical training more than practical application in teaching.	Theory and practice
2	A2	In my opinion, technology-enhanced learning is more successful in integrating Theoretical and practical education compared to traditional classes.	
3	A3	I feel comfortable with practical teaching in an online environment.	
4	A4	Please state your reason for this choice.	
5	A5	I believe having support from instructional assistants in the online environment is beneficial.	
6	B1	Online learning changes the role of an instructor. I am no longer just a knowledge transmitter but also guide and facilitate the learning process for students.	Motivation
7	B2	My aim is to encourage students to have a more active role in the learning process.	
8	B3	At the beginning of an online course, I assess students' short-term and long-term goals and expectations.	
9	B4	I use various elements of the ARCS model to motivate students for better learning in the online environment.	
10	B5	I think students can manage their learning process better when using technology-enhanced learning.	
11	B6	I am interested in using technology-enhanced learning more in my teaching.	
12	B7	University administrators encourage instructors to use online teaching methods.	

13	C1	I believe technology-based learning is effective in providing efficient training in complex skills.	Knowledge, Insight, and Skills
14	C2	I believe technology-based learning is effective in providing efficient training in soft skills.	
15	C12	Online learning is suitable for teaching any type of skill, whether practical or Theoretical.	
16	C13	I believe instructional videos, simulation tools, and virtual or remote labs can assist engineering students in learning essential skills.	
17	D1	Tailoring online education to individual students' interests and abilities is challenging.	Working-life orientation
18	D2	Technology-enhanced learning brings more flexibility to my teaching.	
19	D3	I think our university curriculum needs revision to align more with online learning.	
20	E1	Technology-enhanced learning has increased my motivation to focus teaching on student-centered approaches.	
21	E2	Technology-enhanced learning has led me to use a variety of assessment methods.	Pedagogy
22	E3	In the online learning environment, there is no need to strictly adhere to pedagogical principles in teaching.	
23	E5	I am satisfied with the technical support provided by the university in online education.	
24	E6	Active learning is more effectively implemented in the online learning environment.	
25	E7	Providing timely feedback to students in online education is challenging.	Pedagogy
26	E8	I am more familiar with traditional teaching methods and struggle to adapt to online teaching methods.	
27	E9	I believe technology-enhanced learning does not require specific content and can utilize traditional class content for online teaching.	
28	E10	The university has specific programs to support instructors in enhancing their competencies through new teaching and assessment methods in the online environment.	
29	E11	The university organizes short-term workshops or training sessions to enhance instructors' skills in designing technology-based courses.	Quality of assessment and ICT
30	E12	More preparation is needed for conducting online classes at the university.	
31	E13	I share my opinions with my colleagues regarding research activities.	
32	E14	I share my opinions with my colleagues regarding teaching activities.	
33	E15	I think evaluation processes need to be reviewed to be compatible with online learning.	Response variables
34	E16	In your opinion, which traditional assessment tool(s) can be used in online education?	
35	E17	What support tools and methods have you referred to while implementing technology-enhanced teaching? (Yes/No)	
36	E18	What approach have you used in conducting your online classes?	
37	E19	In your opinion, which approach is more effective for online learning?	Response variables
38	E20	Which Learning Management System (LMS) do you actively use and support?	
39	G1	All instructors should receive training in using online learning management systems.	
40	G2	Online learning management systems are user-friendly.	
41	G3	Have you experienced using virtual labs in your teaching?	
42	G4	I believe virtual labs provide a similar interactive experience to practical classes in engineering and STEM courses.	Response variables
43	G5	Have you experienced using remote labs in your teaching?	
44	F10	Overall, I am satisfied with working with LMS.	
45	F5	In my opinion, assessing students periodically during the term, not just at the end, leads to better learning.	
46	F11	I know how to monitor students' activities using the LMS automated reporting tool.	Response variables
47	H2	I feel satisfied using technology-enhanced learning in Theoretical courses.	
48	H4	I feel satisfied using technology-enhanced learning in practical courses.	
49	H6	I feel satisfied using technology-enhanced learning in Theoretical-practical courses.
