**Abstract:** In the application of video surveillance, reliable people detection and tracking are always challenging tasks. The conventional single-camera surveillance system may encounter difficulties such as narrow-angle of view and dead space. In this paper, we proposed multi-cameras network architecture with an inter-camera hand-off protocol for cooperative people tracking. We use the YOLO model to detect multiple people in the video scene and incorporate the particle swarm optimization algorithm to track the person movement. When a person leaves the area covered by a camera and enters an area covered by another camera, these cameras can exchange relevant information for uninterrupted tracking. The motion smoothness (MS) metrics is proposed for evaluating the tracking quality of multi-camera networking system. We used a three-camera system for two persons tracking in overlapping scene for experimental evaluation. Most tracking person offsets at different frames were lower than 30 pixels. Only 0.15% of the frames showed abrupt increases in offsets pixel. The experiment results reveal that our multi-camera system achieves robust, smooth tracking performance.

**Keywords:** multi-camera; cooperative tracking; PSO; gait recognition

# **1. Introduction**

Video surveillance has attracted widespread attention in the field of biometrics in recent years. Because gait is a biometric feature that can be effectively recognized at a long distance and without attention. In real applications, appearance changes due to changes in viewing angles or walking directions are one of the main difficulties in gait recognition. This is because people can walk freely in any direction within the field of view of a single camera. When people walk out of one camera and then enter another camera, in addition to continuously capturing the same target, the angle of view will also change. When the angle of view is changed, the accuracy of character tracking and gait recognition will be greatly reduced.

This problem can be solved by integrating multiple views of information from multiple cameras [\[1\]](#page-13-0). However, in reality, the development and deployment of multiple views system is a challenging task.

When using a single fixed camera, the foreground person in the image is detected as the region-of-interest (ROI), then continue to track [\[2\]](#page-13-1). In some works, they also used YOLO to track the person in their camera vision [\[3\]](#page-13-2). For a multicamera system, person tracking is much more complex. Many issues may have to be considered, like as: multicamera spatial arrangement [\[4\]](#page-13-3), FOV overlapping cameras [\[5](#page-13-4)[,6\]](#page-13-5) or non-overlapping cameras [\[7](#page-13-6)[,8\]](#page-13-7), whether to use pan-tilt-zoom (PTZ) cameras [\[9,](#page-13-8)[10\]](#page-13-9), how to perform cooperative multicamera tracking when the target leaves the coverage of a camera [\[11,](#page-13-10)[12\]](#page-13-11) and the method of passing tracked object feature between different camera [\[13,](#page-13-12)[14\]](#page-13-13).

#### *2.1. Cameras Network 2.1. Cameras Network*

A robust gait recognition system by distributed cameras network relies on moving A robust gait recognition system by distributed cameras network relies on moving object detection and tracking. Firstly, the system detects persons by performing preprocessing on the newly received image to determine the number of moving persons. Then, the system tracks the moving persons by creating a template of these persons and running a tracking algorithm to determine the person's locations. Finally, the system performs gait a tracking algorithm to determine the person's locations. Finally, the system performs gait recognition. Through cooperative tracking of distributive cameras, the system ensures recognition. Through cooperative tracking of distributive cameras, the system ensures continuous reliable person identification when a person in question leaves an area covered by a camera and enters an area covered by another camera.

Using a camera network to track the target object has two advantages. First, the depth Using a camera network to track the target object has two advantages. First, the depth information of images can be retrieved to solve the problem of the target being occluded. information of images can be retrieved to solve the problem of the target being occluded. Another advantage is that the coverage of multiple cameras is wider than that of a single Another advantage is that the coverage of multiple cameras is wider than that of a single camera. The tracking mode of the camera network is roughly divided into three types: (1) camera. The tracking mode of the camera network is roughly divided into three types: (1) Object tracking of images in different hours, (2) object tracking of overlapped FOVs and Object tracking of images in different hours, (2) object tracking of overlapped FOVs and (3) (3) object tracking of nonoverlapped FOVs. object tracking of nonoverlapped FOVs.

Techniques such as graph generation [15] and person reidentification model [16] can Techniques such as graph generation [\[15\]](#page-13-14) and person reidentification model [\[16\]](#page-13-15) can help the system construct 3D models without manual calibration and the models can be help the system construct 3D models without manual calibration and the models can be used to facilitate multi-camera object tracking in overlapped FOVs (Figur[e 2](#page-2-0)). All the used to facilitate multi-camera object tracking in overlapped FOVs (Figure 2). All the aforementioned approaches are to calculate the absolute position of a detected object and aforementioned approaches are to calculate the absolute position of a detected object and adopt the resultant absolute position as a feature to determine whether the detected object adopt the resultant absolute position as a feature to determine whether the detected object is the target. is the target.

In the aforementioned multicamera tracking methods, object tracking is performed using the overlapped images captured by fixed cameras. Benito-Picazo et al. [\[17\]](#page-13-16) use fixed cameras and PTZ cameras to capture overlapped images for object tracking. The methods use a surveillance system that employs both static and active cameras with panning, tilting and zooming functions. The most noticeable difference between this type of multicamera tracking technique and other tracking techniques is that the multicamera system can rotate and enlarge surveillance images by using active cameras. Thus, the multicamera system can more effectively monitor the objects of interest in a surveillance environment and achieve comprehensive active surveillance.

<span id="page-2-0"></span>

Figure 2. Multicameras scene model (a) FOV lines and projections (b) Graph Generation. Figure 2. Municality secretation (a)  $1 \vee r$  lines and  $p_1$ 

Because of the deployment complexity and resource constraints, the camera networkbased tracking method with highly overlapping FOVs cannot be realized easily in reality. The cameras network we designed was aimed to expand view coverage instead of overlapping FOVs. Therefore, in the proposed camera network-based tracking method, we must strive to extract the information of the extracted object, namely time, velocity, motion path and object features, to obtain the relative positions of the monitored object captured by different cameras. This study also focused on developing an object tracking approach in which the FOVs of multiple cameras are partially overlapped to ensure continuous and robust tracking.

The setup of multiple cameras influences the extent to which the coverage areas are overlapped. For example, if the areas monitored by cameras are mostly overlapped, the collected depth information of the target object can be relatively accurate; however, data redundancy is also likely. By contrast, if the areas covered by cameras do not overlap with one another [[18\],](#page-13-17) the scenario is similar to that of using a single fixed camera. To find a balance between the two aforementioned setups, we use a setup with partially overlapping coverage areas (Fi[gu](#page-2-1)re 3).

<span id="page-2-1"></span>

Figure 3. Cameras Network with partially overlapping coverage areas.

study used corner features to acquire the information of overlapped images. To determine The setup we chose has two advantages. When coverage areas of cameras are overlapped, depth information can be obtained. Moreover, the FOVs for the coverage areas can be expanded. Differing from most multicamera systems that require high levels of overlap to accurately set parameters and construct 3D models, this study focused on expanding the view coverage of the designed system. Therefore, construction of 3D scenes and depth information were not required. The system only has to draw demarcations for coverage areas that were overlapped in a binary image. This indicated that the system obtains labeled regions of cameras by simply extracting corner features and matching those features. This a corner feature, the difference between the brightness of the central detection pixel  $(x, y)$  and that of the neighboring pixels w[as](#page-3-0) calculated. Figure 4 shows the corner detection in different camera views.

# 2.1.2. Person Tracking 2.1.2. Person Tracking 2.1.2. Person Tracking

After completing object detection, the system collected the template features of the extracted moving object. The system searched for the target object and identified the target's position among a continuous series of images. We ran the aforementioned PSO algorithm [20] to detect and track the moving object. Figure 7 ex[hi](#page-4-1)bits the process of object tracking.

<span id="page-4-1"></span>

**Figure 7.** Person Tracking. **Figure 7.** Person Tracking. **Figure 7.** Person Tracking.

When performing PSO-based tracking, particles were randomly distributed in an image during initialization. The system then determined the optimal solution according to the positions of current particles and corrected the positions for subsequent iterations. Multiplying the number of particles by the frequency of iterations yields the number of comparisons. In this study, we performed 10 iterations on 50 particles to achieve particle convergence, which was equivalent to 500 comparisons. Compared with universal search, PSO can perform more efficient searches and comparisons.

To acquire efficient and accurate search results, particles were not distributed throughout the entire image once the position of the target was determined. Instead, the particles

were distributed in a limited manner around the current target. By utilizing the objects movement continuity, the system distributed particles within the predicted target range to more efficiently track the target object.

#### *2.2. Cooperative Tracking*

When a moving object is about to leave the area covered by a camera, ensuring continuous and stable tracking is a crucial goal of a cooperative multicamera tracking system.

This paper presents a novel approach to transferring tracking tokens from camera to camera that entails a three-step process for achieving cooperative multicamera tracking and is detailed as follows.

Step 1: Entrance of a moving object into the demarcation area

We establish that the camera monitoring and tracking the moving object has the tracking token. When the object enters the demarcation area (i.e., the overlapping area between the camera with token and another camera), the camera with token calls another camera and informs it that the object is about to enter its FOV.

Step 2: Detection of the moving object

After the moving object enters the demarcation area (i.e., overlap area) and another camera is called, the system extracts the current foreground object and establishes a template model. Subsequently, the system determines whether this foreground object is the moving object tracked by the previous camera according to time features (i.e., the time that the object enters the demarcation region). The system determines this using the following formula:

$$
C(\text{cam1, cam2}) = \begin{cases} 1, T(obj, cam1) = T(obj, cam2) \\ 0, otherwise \end{cases}
$$
 (1)

$$
L(D, C) = \begin{cases} 1, & C = 1 \text{ and } D < \varepsilon \\ 0, & otherwise \end{cases}
$$
 (2)

We assume that *T(obj, cam no.)* is the time that the moving object enters the demarcation area and *C(cam no., cam no.)* is the result that depends on whether the times detected by two cameras are the same. This rule-of-time feature determination is incorporated with the difference of color feature vectors *D*. A difference lower than the threshold indicates high similarity between the detected objects. *L(*D, C) is used to verify whether the currently detected object is the previously detected moving object following the time feature *C* and color feature of the moving object.

Step 3: Transfer of tracking tokens

Following from Step2, if the system determines that the currently detected object is the moving object detected by the previous camera (Camera 1), the previous camera will transfer the tracking token to the current camera (Camera 2). The system can thus continue to track the object in question. Conversely, if the system finds that the two detected objects are different, it identifies the currently detected object as a new moving object. Camera 2 then begins to track this object and owns the tracking token for it. The cooperative tracking protocol between cameras is depicted in Figure [8.](#page-6-0)

#### *2.3. Gateway*

In order to manage all of distributed cameras and perform person tracking and detection, we design a system as Figure [9](#page-6-1) to get the image data and run the tracing task on it.

The gateway is composed of gateway master node and AI hardware acceleration nodes. When the camera finished image capture, it will send the data to the gateway. The master node has two functions: distribute data to idle AI hardware acceleration nodes and establish connection between each camera to let them communicate with the gateway. Firstly, the master node receives data flow and check which deep learning worker node is in the idle state, then master node will forward data to the idle node. When the computation

<span id="page-6-0"></span>of deep learning worker nodes is completed, they send the result back to gateway and the gateway will keep this feature in order to track the same object between different cameras.

Camera 2 create new template to track new person

**Figure 8.** Cooperative Tracking between cameras. **Figure 8.** Cooperative Tracking between cameras.

<span id="page-6-1"></span>

#### $\bf{results}$ **3. Results**

During the experiment, we use raspberry pi camera module v2 as our IoT camera. In addition, we set these modules working at 720p resolution, to perform our real time image expturing task. The matrix of the gateway. The gateway of the gateway. The gateway

The analysis and accuracy test was conducted on the developed cooperative tracking employed to evaluate tracking accuracy. MS evaluates the tracking accuracy of a system by measuring the offset of the tracked object and the formula is as follows [22]:  $\mathbf{u}$ algorithm. The non-ground-truth (NGT) measure motion smoothness (MS) [21] was

$$
MS(t) = d_E(T(t), T(t - \Delta)) = \sqrt{(x(t) - x(t - \Delta))^2 + (y(t) - y(t - \Delta))^2}
$$
(3)

where  $\rm{d_{E}}$  denotes the Euclidean distance between the positions of the moving object being tracked over two consecutive frames,  $T(t)$  is the position of the tracked object at t hour and represents the time interval. A high value of MS indicates that the moving distance of the tracked object has experienced great changes, whereas a low MS value indicates a<br>algorithm small offset. The offset of a person is normally not large. Accordingly, when the MS curve abruptly lifts or drops, a tracking error is likely. Another explanation for an abrupt increase abruphy ints or drops, a tracking error is likely. Another explanation for an abrupt increase<br>or decrease is that the object actually has a large offset. Conversely, a smooth MS curve indicates a small offset, revealing that the system is stably tracking the object. During the experiment, we use raspberry pi camera module v2 as our IoT camera. In  $\alpha_{\rm E}$  denotes the Euchdean distance between the positions of the moving object being

In the resultant curve diagram, the *x*-axis represents the image frame, which can also be regarded as timeline and the *y*-axis represents the tracking quality. MS measurement was used to calculate the offsets of tracked objects.

A smooth curve without abrupt lift or drop indicates that the tracked object has a small offset and that the tracking is stably in progress. We assessed the quality of multicamera tracking by creating scenarios of one person, two persons and two persons with overlapped. When the moving object entered the demarcation area, another camera communicated with the previous camera and took over the tracking token through a protocol to continue tracking and analyzing the detected object. Additionally, when the numed in the state of the demarcation area, we observed whether the mechanism of vertex the image frame, which can also represents the mechanism of cooperative communication was initiated between cameras and whether the tracking token was transferred to achieve continuous tracking.

#### *3.1. Tracking of One Person*

The images in Figure [10](#page-7-0) present the scenes where a person walked through the coverage of Camera 1, Camera 2 and Camera 3 and then returned to the coverage of Camera 2. This scenario was designed to assess the performance of the tracking system in a simple situation. Figure 11. presents the evaluation of the tracking results. The results in Figure 12 showed that the curve was mostly steady until the pixel values suddenly soared at Frame nos. 260~275 under the coverage of Camera 3. We extracted these frames for further analysis as Figure  $11$ .

According to the results depicted in Figure [11,](#page-8-0) the system successfully tracked the person between Frame 260 and Frame 275, but the search boxes were not in optimal positions, which caused pixel values to abruptly increase. Regarding cooperative multicamera tracking, the pictures in 12 depict the target (Object 1) entering the demarcation area at Frame no. 57. Camera 2 detected the new moving object and labeled it as Object 2. However, according to the proposed cameras network protocol, the system determined that Object 2 was actually the object detected by Camera 1. Therefore, Camera 1 passed the tracking token to Camera 2 at Frame no. 58 and Camera 2 changed the label of the target from Object 2 to Object 1 and continued the tracking work.

<span id="page-7-0"></span>

*3.2. Tracking of Two People 3.2. Tracking of Two People*

Figure 13 presents the scenes where two peoples separately started their journeys from the scenes covered by Camera 1 and Camera 3 (Object 1 from Camera 1 and Object 2 from the scenes covered by Camera 1 and Camera 3 (Object 1 from Camera 1 and Object from Camera 3). Object 1 was the tracked object being occluded (i.e., when the two peoples  $20$  from Camera 3). Object 1 was the tracked object being occurred (i.e., when the two peopassed each other, Object 1 was occluded by Object 2). This scenario was created to assess whether the designed algorithm can accurately track an occluded object. Figure [13](#page-8-2) presents the scenes where two peoples separately started their journeys

<span id="page-8-2"></span>

**Figure 13.** Three cameras view for two peoples tracking. **Figure 13.** Three cameras view for two peoples tracking.

In the experiment, the system tracked two people. When the system tracked two people, the assessed algorithm could maintain its tracking accuracy compared with single people tracking. Figure [14a](#page-9-0),b left picture exhibits the MS curves of Objects 1 and 2, respectively. Most object offsets at different frames were lower than 30 pixels. Only several frames showed abrupt increases in pixel values. For example, Figure [15a](#page-9-1) depicts an abrupt increase at Frame no. 61 and Frame no. 90.

<span id="page-9-0"></span>

<span id="page-9-1"></span>

**Figure 14.** Tracking token transfer between Cam1 and Cam2 in single person tracking scene. **Figure 15.** Tracking token transfer between Cam1 and Cam2 in single person tracking scene.

the image of the object was incomplete and caused a tracking error. The system then As shown in Figure [16,](#page-10-0) from Frame no. 114 to Frame no. 129, Object 1 (in the yellow box) and Object 2 (in the green box) passed each other under the coverage of Camera 2, during which time Object 1 was occluded by Object 2. After the people separated, the cameras again captured their targets. The MS curve of Object 2 (Figure [15b](#page-9-1)) abnormally rose at Frame no. 193. To examine this situation, we analyzed the images of relevant frames (Figure [17\)](#page-10-1) and discovered that the abnormal increase occurred when the target had just entered the surveillance area (entering the area from the edge). Under such a circumstance, corrected the error, thus leading to an abrupt offset increase. Figure [18](#page-11-0) shows the tracking privilege transfer between cameras. Regarding cooperative tracking of cameras network,

the people detected by Camera 2 was labeled as Object 1, but Camera 3 labelled this people as Object 5 at Frame no. 128. At this moment, the privilege transfer protocol allowed Camera 3 to take over the tracking privilege from Camera 2, fix the error and change the label of this People back to Object 1 at Frame no. 129.

# *3.3. Tracking of Two Persons in Overlapped Scene*

Figure [19](#page-11-1) presents the scenario where two persons jointly set off from the scene covered by Camera 1 and reached the scene of Camera 3 with different walking speeds. Because Object 1 was on the left of Object 2 (i.e., Object 1 was farther from the cameras compared with Object 2), it was sometimes occluded by Object 2. This scenario was created to assess the tracking performance of the designed algorithm in a unique situation.

<span id="page-11-0"></span>

**Figure 18.** two people privilege transfer between cameras. (**a**) Person 1 heading right and keep walking until enter different walking until enter different camera vision in (b). (b) The camera in (a) will relay information of person 1 to camera in (**b**), so the camera in (**b**) can keep tracking. Figure 18. Two people privilege transfer between cameras. (a) Person 1 heading right and keep

<span id="page-11-1"></span>

**Figure 19.** Two persons tracking in overlapping scene. **Figure 19.** Two persons tracking in overlapping scene.

This test image shows two people starting from Cam1 at the same time and walking to Cam3 at different speeds and Object1 is a tracked object standing behind and obscured (Object2 standing in front).

Because of the occlusion effect, the occluded target exhibited greater MS curve fluctuations in the evaluation. Specifically, the curves in Figures [19](#page-11-1) and [20](#page-12-0) left exhibit more sudden increases compared with the MS curves in the aforementioned single person and two-persons situations.

In the experiment, the system tracked two persons. When the system tracked two persons, the assessed algorithm could maintain its tracking accuracy compared with single person tracking. Figure [20a](#page-12-0),b exhibit the MS curves of Objects 1 and 2, respectively. Most object offsets at different frames were lower than 30 pixels. Only 0.15% of frames showed abrupt increases in offset pixel.

PSO-based algorithm could not accurately identify the position of an occluded target, it continued to identify and track the target when the occlusion disappeared. Even the human eye has difficulty conforming that an occluded object is the target. In this scenario*,* one can When the two persons were walking parallel to each other, the person occluded by his counterpart could not be accurately tracked because most of his body was occluded for a while. Nevertheless, once the occlusion was gone (i.e., the two persons separated), we could again detect the positions of these two persons. Although the system using the only recognize the target by using logical cognition to analyze the positions of an object in

### **4. Conclusions**

In this paper, we proposed a cameras network architecture and the hand-off protocol for cooperative people tracking and also designed a reliable and highly efficient algorithm that enables real-time people detection and tracking. YOLO object model is used to detect the peoples in the video scene, when a person leaves the FOV area covered by a camera and enters an FOV area covered by another camera, these cameras can exchange relevant information for uninterrupted tracking. By incorporating a particle swarm optimization algorithm, our system can perform robust inter-camera tracking using multiple cameras system. The motion smoothness (MS) metrics is proposed for evaluating the tracking quality of multi-camera networking system. For experience, we used a three-camera system for two persons tracking in overlapping scene. Most tracking person offsets at different frames were lower than 30 pixels. Only 0.15% of frames showed abrupt increases in offsets pixel. The experiment results reveal that the approach we adopted achieves superior tracking performance.

**Funding:** This study was supported by the Investigation Bureau, Ministry of Justice, R.O.C., grants No. 109-1301-05-17-02.

**Institutional Review Board Statement:** The study was conducted according to the guidelines of the Declaration of Helsinki, and approved by the Ethics Committee of National Taiwan University Behavior and Social Science Research Ethics Committee (protocol code 202007ES034, 18 August 2020).

**Informed Consent Statement:** Informed consent was obtained from all subjects involved in the study.

**Conflicts of Interest:** The authors declare no conflict of interest.
