**Abstract:** With the rapid development of cloud computing and mobile networks, more and more application scenarios require a secret group key for secure communication. Group Key Exchange (GKE) protocol provides a secret group key for three or more members. Burmester and Desmedt presented an influential GKE protocol, which has a broadcast version and a cyclic version. In this paper, we investigate the security weaknesses of the Burmester-Desmedt protocol. We report that both the broadcast version and the cyclic version of the Burmester-Desmedt protocol suffer member tampering attacks if the two members that belong to both group *A* and group *B* are corrupted. That is, two corrupted members can add some unknowing members of group *A* to group *B* and trick the legal members of group *B* to believe that these unknowing members share the secret group key with them after a protocol run. Furthermore, to defeat the member tampering attack, we propose digital signature-based improvements on the broadcast version and the cyclic version of the Burmester-Desmedt protocol. We hope our research results will encourage the development of more robust and effective GKE protocols that stand rigorous security analysis.

## 1. Introduction

Group Key Exchange (GKE) protocol makes an extension for the traditional two-member key establishment [1]. The function of the GKE protocol is to provide a shared secret group key for three or more members. With the rapid development of cloud computing and mobile networks, more and more application scenarios require group communication. Naturally, the security of group communication depends on the security of the group key [2,3]. We can summarize the general requirements of the GKE protocols as follows.

- (1) Members in various groups generate different shared secret group keys (also named group session keys).
- (2) The group session key is dynamic and can be updated as needed.
- (3) The protocol messages exchanged among the members are open and via the public channel.
- (4) Each member calculates his group session key independently.

To realize group key generation, an obvious method is to deploy a Trusted Third Party (TTP) recognized by all members in a group communication system. Moreover, each member shares a secret key with the TTP in advance. When the group session key needs to be established, the TTP randomly generates a group session key, determines the group of members and encrypts the group session key by using the shared secret key with each member. Upon receiving the ciphertext of the group session key, each member in the group can decrypt it using his shared key and obtain the group session key. The disadvantage of this method is that there must be a TTP to provide group key generation

services for all members in real-time. That is, the online TTP means heavy computation and communication overhead and may become the technical bottleneck.

Another optional method that does not require a TTP is to choose a member of the group as the group controller. The group controller negotiates a secret Diffie-Hellman key [4] with each member of the group. Then, the group controller randomly generates a group session key, uses each Diffie-Hellman key to encrypt the group session key, and sends it to each member of the group. After receiving the ciphertext of the group session key, the members can respectively decrypt the group session key using its own Diffie-Hellman key. The disadvantage of this method is that the large overhead of computation and communication is a burden on the group controller, and the members of the group need to designate a group controller before the group key generation services.

In this paper, we investigate the GKE protocols based on generalizing Diffie-Hellman two-member key exchange [4], because such protocols can potentially avoid the TTP or the group controller. This is a desirable feature under decentralized computing environments such as ad hoc networks and Blockchain.

### 1.1. Basic Notion of Group Key Exchange

Let  $k$  be a security parameter and  $U_1, U_2, \dots, U_n$ ,  $n = \text{poly}(k)$  (a polynomial in the security parameter  $k$ ), be members that are allowed to take part in a specified GKE protocol  $P$  to generate a group session key  $K$ . We can define the GKE protocol as follows.

**Definition 1.** Protocol  $P$  is called a GKE if: when a group of any  $t$  members has honestly executed the protocol  $P$  as specified, then each member  $U_i$  in the group will finally compute his own session key  $K_i$  such that  $K = K_i$ , where  $3 \leq t \leq n$  and  $i \in \{1, 2, \dots, n\}$ .

Assume that any GKE protocol  $P$  runs on public networks in which all members in a group can broadcast or send messages (bit strings) to other members in the presence of a (polynomially bounded) passive adversary  $E$ . Passive adversary  $E$  can eavesdrop on the transmitting messages and keep a log of the messages during past protocol runs. However, the passive adversary  $E$  does not modify the transmitting messages of protocol runs. A formal security definition as an example is presented to address the above passive adversary of the GKE protocol  $P$  [5] as follows.

**Definition 2.** The GKE protocol  $P$  guarantees privacy if it is computationally infeasible for the passive adversary  $E$  to compute the group session key  $K$ . The GKE protocol  $P$  guarantees secrecy if the passive adversary  $E$  cannot distinguish the group session key  $K$  from a random bit string of the same length with probability better than  $1/2 + \epsilon$ , where  $\epsilon$  is negligible (in the security parameter  $k$ ).

### 1.2. Related Work

Some of the literature in the GKE domain mainly revolves around the exposition of new construction of the GKE protocols. An early investigation of GKE protocols by Ingemarsson, Tang, and Wong [6] described a number of so-called Diffie-Hellman generalizations based on the idea of symmetric functions. Steer et al. [7] gave other GKE protocols generalizing the Diffie-Hellman two-member key exchange. Their protocol is suitable for adding new group members; however, deleting members is relatively difficult. Later, Steiner, Tsudik, and Waidner [8] presented three GKE protocols (named GDH.1, GDH.2, and GDH.3) to improve the communication and computation costs of the Ingemarsson-Tang-Wong GKE protocols. Kim, Perrig, and Tsudik [9], and Bresson and Manulis [10] considered tree-based Diffie-Hellman two-member key exchange and showed that their protocols are very suitable when the composition of the group is changed without restarting the whole protocol. Burmester and Desmedt [5] presented an influential GKE protocol by extending in a natural way of the Diffie-Hellman two-member key exchange. Harn and Lin [11], Harn and Hsu [12] proposed GKE protocols based on both the secret sharing scheme and the group Diffie-Hellman key exchange scheme. Moriya, Takashima, and Takagi [13] and Fan,

Xu, and Li [14] proposed the GKE protocols based on Commutative Supersingular Isogeny Diffie-Hellman (CSIDH), which are the post-quantum Diffie-Hellman type key exchange protocols from commutative group action.

Some of the literature in the GKE domain research on the security analysis of the GKE protocols. Katz and Yung [15] presented a compiler that transforms the GKE protocol secure against a passive adversary and proved the Burmester-Desmedt protocol secure against the passive adversary. Emmanuel, Chevassut, and Pointcheval [16] provided a formal security model and several security definitions, which are adapted to many cryptographic scenarios for authenticated Diffie-Hellman key exchange in a group. To prevent stronger attacks against honest but open members, Bresson, Manulis, and Schwenk [17] gave examples where  $m$  uncorrupted members accept each other but have different session keys. Gorantla, Boyd, and Nieto [18] specifically analyzed the security of the GKE protocol under the key-compromise impersonation attacks. Baouch et al. [19] introduced an active attack on the Burmester-Desmedt protocol, that is, the adversary can obtain a copy of the shared key, which is created in a collaborative manner with the legal members in a group. Yang et al. [20] presented a security model for generic dynamic authenticated GKE to cover more active attacks (such as leakage of the ephemeral secret key) than previous similar models. As another line of security analysis work on GKE, Cohn-Gordon et al. [21] considered the post-compromise security of group messaging, that is, an adversary who compromises a single group member can indefinitely read and inject messages and built a formal security model on the ideas of multi-stage key exchange by Fischlin and Günther [22]. Alwen et al. [23] further analyzed the TreeKEM protocol [24], which is proposed by the Internet Engineering Task Force (IETF) working group and is the core of the secure group messaging protocols on message-layer security. Alwen et al. [25] also defined optimal security notions for GKE and considered two settings, i.e., the passive setting and the active setting. In addition, Hougaard and Miyaji [26] recently proposed a GKE compiler using any two-member key exchange for which the shared key space is the subset of a group and whose security reduces to the Decisional Diffie-Hellman (DDH) problem. Poettering et al. [27] classified characteristics of a large selection of game based GKE models, including those proposed for GKE with post-compromise security, and observed a range of shortcomings in some of the studied models.

### 1.3. Our Motivations and Contributions

When a GKE protocol is running, the adversary may illegally add some dummy members to the group. Although these dummy members do not belong to the group, the legal members believe that they are in the group and share a group session key with them. We call it the member tampering attack. To the best of our knowledge, the member tampering problem of the GKE protocol has not been studied yet. It is widely known that the Burmester-Desmedt protocol has advantages over other existing GKE protocols in terms of computation cost, communication cost, and the number of rounds. Moreover, since broadcasting messages can be expensive in some communications networks, the Burmester-Desmedt protocol [1,5] has not only a broadcast version but also a cyclic version. Therefore, we investigate the member tampering attack on the broadcast version and cyclic version of the Burmester-Desmedt protocol. We report that both the broadcast version and cyclic version suffer the member tampering attack when two members are corrupted. That is, two corrupted members, who belong to two groups  $A$  and  $B$ , can collude to include some unknowing members of group  $A$  into the group  $B$  and cheat other legal members of the group  $B$  to believe that these unknowing members exist in their group and share a group session key after the protocol run.

## 2. Review of the Burmester-Desmedt Group Key Exchange Protocol

Burmester and Desmedt [5] employed a certain structure of the cyclic group to design their GKE protocol. Without loss of generality, we can write it as follows. Let  $G$  be a cyclic group with prime order  $q$  and let  $g$  be a fixed generator of  $G$ . Let  $Z_p = Z/pZ$  be the integers

modulo  $p$ . The cyclic group requires choosing two primes  $p$  and  $q$  such that  $q \mid p-1$  and a generator  $g \in Z_p$  with the order  $q$ . Then, the cyclic group is formed by  $G = \{g^x \bmod p, x \in Z\}$ .

Assume that  $U_1, U_2, \dots, U_n$  are all legal members of the GKE system. Initially, a GKE center chooses the system parameters for the GKE protocol. That is, the GKE center determines a security parameter  $k$  and a constant  $c \geq 1$ , randomly generates a prime  $p = \Theta(2^{ck})$  and an element  $g \in Z_p$  of order  $q = \Theta(2^k)$ , where  $\Theta$  denotes asymptotic tight bound, and publishes the parameters  $p, g$ , and  $q$  to build the cyclic group  $G$ . Let  $U_1, U_2, \dots, U_t \leq n$  be a group of members who want to generate a group session key  $K$ . To enable a general description, we always allow any index  $i$  but  $U_i$  and  $U_j$  are the same members when satisfying  $i = j \bmod t$ .

### 2.1. Broadcast Version

The Burmester-Desmedt protocol is simplest to describe in the version that allows broadcast communications. Here, any message sent to more than one member means the broadcast.

#### Protocol 1: Broadcast version

Round 1. Each member  $U_i$  ( $i = 1, 2, \dots, t$ ) selects a random  $r_i \in Z_q$  and computes and broadcasts  $z_i = g^{r_i} \bmod p$ .

Round 2. Each member  $U_i$  ( $i = 1, 2, \dots, t$ ) computes and broadcasts  $X_i = (z_{i+1}/z_{i-1})^{r_i} \bmod p$ .

Key Computation. Each member  $U_i$  ( $i = 1, 2, \dots, t$ ) computes his own session key:

$$K_i = (z_{i-1})^{tr_i} X_i^{t-1} X_{i+1}^{t-2} \dots X_{i-2} \bmod p. \tag{1}$$

Figure 1 shows the communication and computation of broadcast version. If each member  $U_i$  ( $i = 1, 2, \dots, t$ ) honestly generates and broadcasts his  $z_i$  and  $X_i$ , all members will secretly share the same group session key  $K = g^{r_1 r_t + r_1 r_2 + r_2 r_3 + \dots + r_{t-2} r_{t-1} + r_{t-1} r_t} \bmod p$ . That is to say, for every member  $U_i$  ( $i = 1, 2, \dots, t$ ), we have

$$\begin{aligned} K_i &= (z_{i-1})^{tr_i} X_i^{t-1} X_{i+1}^{t-2} \dots X_{i-2} \bmod p = \\ &= (z_{i-1})^{tr_i} \left(\frac{z_{i+1}}{z_{i-1}}\right)^{(t-1)r_i} \left(\frac{z_{i+2}}{z_i}\right)^{(t-2)r_{i+1}} \dots \left(\frac{z_{i-1}}{z_{i-3}}\right)^{r_{i-2}} \bmod p = \\ &= (g^{r_{i-1}})^{tr_i} \left(\frac{g^{r_{i+1}}}{g^{r_{i-1}}}\right)^{(t-1)r_i} \left(\frac{g^{r_{i+2}}}{g^{r_i}}\right)^{(t-2)r_{i+1}} \dots \left(\frac{g^{r_{i-1}}}{g^{r_{i-3}}}\right)^{r_{i-2}} \bmod p = \\ &= (g^{r_{i-1}})^{r_i} (g^{r_{i+1}})^{r_i} (g^{r_{i+2}})^{r_{i+1}} \dots (g^{r_{i-3}})^{r_{i-2}} (g^{r_{i-1}})^{r_{i-2}} \bmod p = \\ &= g^{r_1 r_t + r_1 r_2 + r_2 r_3 + \dots + r_{t-2} r_{t-1} + r_{t-1} r_t} \bmod p = K \end{aligned} \tag{2}$$

### 2.2. Cyclic Version

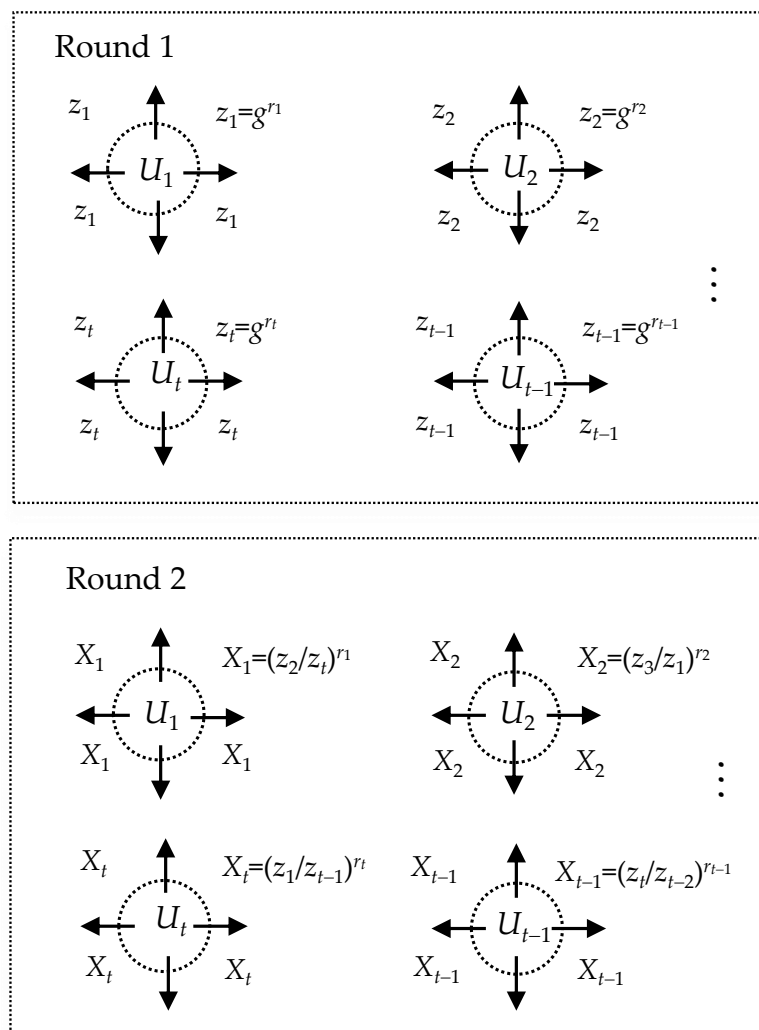

In the broadcast version, the protocol messages always need to be sent to all of the members. In some communications environments such as wired communications, the broadcast of messages to all involved members may be more costly than sending them to a single member. Therefore, the cyclic version can maintain the same Diffie-Hellman generalization function as the broadcast version but implement the point-to-point message transmission among the members.

#### Protocol 2: Cyclic version

Round 1. Each member  $U_i$  ( $i = 1, 2, \dots, t$ ) selects a random  $r_i \in Z_q$ , and then computes and sends  $z_i = g^{r_i} \bmod p$  to the members  $U_{i-1}$  and  $U_{i+1}$ .

Round 2. Each member  $U_i$  ( $i = 1, 2, \dots, t$ ) computes  $X_i = (z_{i+1}/z_{i-1})^{r_i} \bmod p$ . Let  $b_0 = c_0 = 1$ . For  $i = 1$  to  $t$ , the member  $U_i$  computes  $b_i = b_{i-1} X_i \bmod p$  and  $c_i = b_{i-1} c_{i-1} \bmod p$ , and then sends  $b_i$  and  $c_i$  to the member  $U_{i+1}$ .

Round 3. Let  $d_0 = c_t$  and  $d = b_t$ . For  $i = 1$  to  $t - 1$ , the member  $U_i$  computes  $d_i = d d_{i-1} X_i^{-t} \bmod p$ , and then sends  $d_i$  and  $d$  to the member  $U_{i+1}$ .

Shared session key:  $K = K_i = (z_{i-1})^{tr_i} X_i^{t-1} X_{i+1}^{t-2} \dots X_{i-2} \text{ mod } p$ , where  $i = 1, 2, \dots, t$

Figure 1. Communication and computation of broadcast protocol.

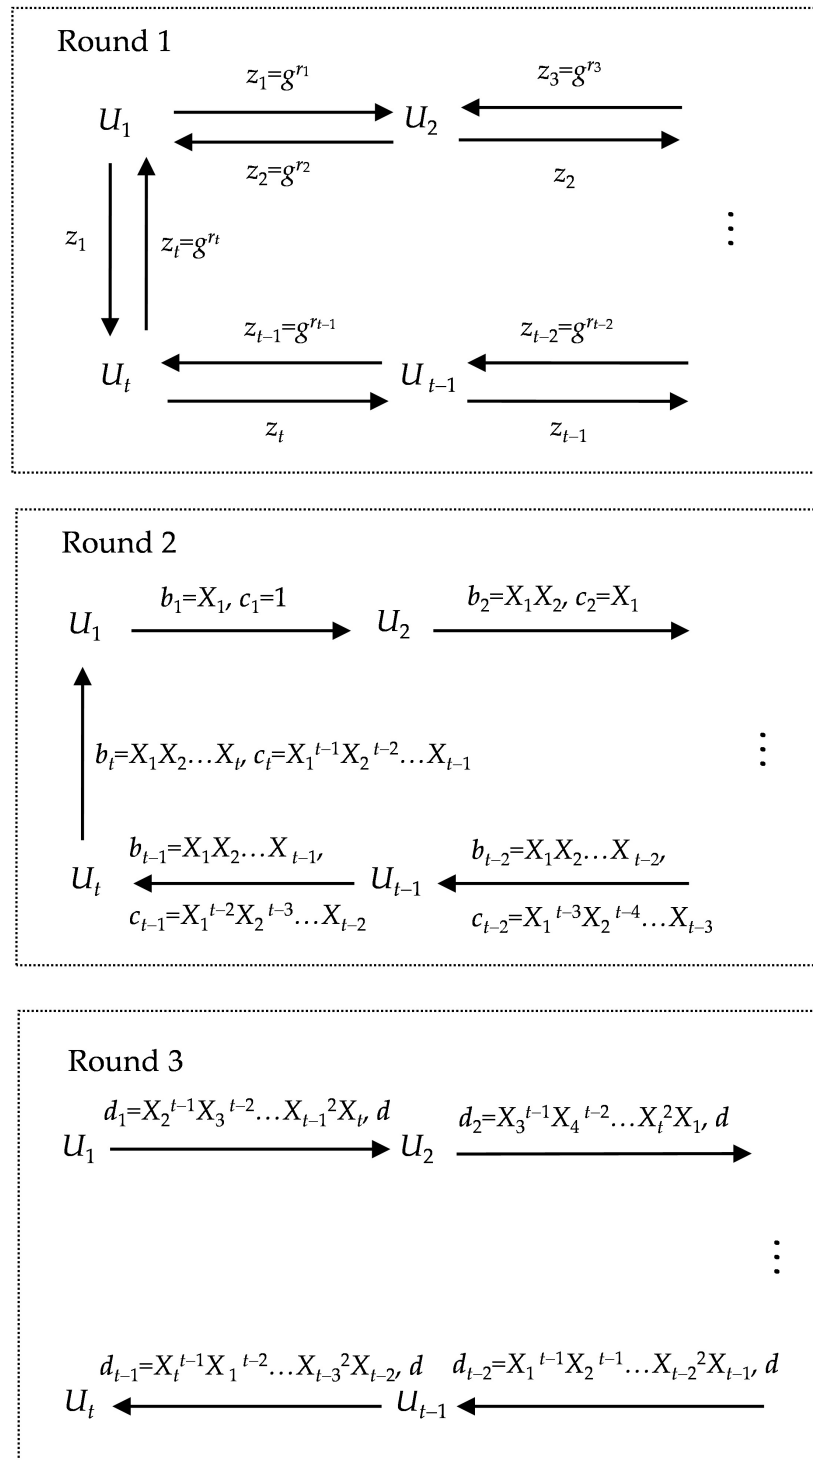

Key Computation. Each member  $U_i$  ( $i = 1, 2, \dots, t$ ) computes his own session key:

$$K_i = (z_{i-1})^{tr_i} d_{i-1} \text{ mod } p. \tag{3}$$

It is easily to see that cyclic version does not require the broadcast channel. We know that in Round 2,  $b_0 = c_0 = 1, b_1 = b_0 X_1 = X_1 \text{ mod } p, c_1 = b_0 c_0 = 1, b_2 = b_1 X_2 = X_1 X_2 \text{ mod } p, c_2 = b_1 c_1 = X_1 \text{ mod } p, b_3 = b_2 X_3 = X_1 X_2 X_3 \text{ mod } p, c_3 = b_2 c_2 = X_1^2 X_2 \text{ mod } p, \dots, b_t = b_{t-1} X_t = X_1 X_2 \dots X_t \text{ mod } p, c_t = b_{t-1} c_{t-1} = X_1 X_2 \dots X_{t-2} X_{t-1} X_1^{t-2} X_2^{t-3} \dots X_{t-2} = X_1^{t-1} X_2^{t-2} \dots X_{t-2}^2 X_{t-1} \text{ mod } p$ . Since  $d_0 = c_t = X_1^{t-1} X_2^{t-2} \dots X_{t-1} \text{ mod } p$  and  $d = b_t = X_1 X_2 \dots X_t \text{ mod } p$  during Round 3, we get  $d_1 = d d_0 X_1^{-t} = X_1 X_2 X_3 \dots X_{t-1} X_t X_1^{t-1} X_2^{t-2} X_3^{t-3} \dots X_{t-1} X_1^{-t} = X_2^{t-1} X_3^{t-2} \dots X_{t-1}^2 X_t \text{ mod } p, d_2 = d d_1 X_2^{-t} = X_1 X_2 X_3 X_4 \dots X_t X_2^{t-1} X_3^{t-2} X_4^{t-3} \dots X_t X_2^{-t} = X_3^{t-1} X_4^{t-2} \dots X_t^2 X_1 \text{ mod } p, \dots, d_{t-1} = d d_{t-2} X_{t-1}^{-t} = X_1 X_2 \dots X_{t-3} X_{t-2} X_{t-1} X_t X_{t-1}^{t-1} X_t^{t-2} X_1^{t-3} X_2^{t-4} \dots X_{t-3} X_{t-1}^{-t} = X_t^{t-1} X_1^{t-2} X_2^{t-3} \dots X_{t-3}^2 X_{t-2} \text{ mod } p$ . We therefore know  $d_{i-1} = X_i^{t-1} X_{i+1}^{t-2} \dots X_{i-2} \text{ mod } p$ , where  $i = 1, 2, \dots, t$ . Thus, for all  $1 \leq i \leq t$ , it follows that

$$K_i = (z_{i-1})^{tr_i} d_{i-1} \text{ mod } p = (z_{i-1})^{tr_i} X_i^{t-1} X_{i+1}^{t-2} \dots X_{i-2} \text{ mod } p = g^{r_1 r_i + r_1 r_2 + r_2 r_3 + \dots + r_{i-2} r_{i-1} + r_{i-1} r_i} \text{ mod } p = K. \tag{4}$$

Hence, we conclude that all members in cyclic version can finally share the same group session key as broadcast version. Figure 2 shows the communication and computation of cyclic version.

Shared session key:  $K = K_i = (z_{i-1})^{tri} d_{i-1} \text{ mod } p$ , where  $i = 1, 2, \dots, t$

Figure 2. Communication and computation of cyclic protocol.

### 2.3. Security Results

The security of the Burmester-Desmedt protocol depends on the Computational Diffie-Hellman (CDH) problem and the DDH problem. We describe the CDH problem and the DDH problem as follows.

**Definition 3.** The CDH problem: given two primes  $p$  and  $g$  and two random numbers  $x = g^a \pmod p$ ,  $y = g^b \pmod p$ , find  $g^{ab} \pmod p$ .

**Definition 4.** The DDH problem: given two primes  $p$  and  $g$  and three random numbers  $x = g^a \pmod p$ ,  $y = g^b \pmod p$ , and  $z = g^c \pmod p$ , decide if  $ab = c$ .

The Burmester-Desmedt protocol achieves the following security properties [5].

**Fact 1.** Protocol 1 and Protocol 2 guarantee the privacy as in Definition 2 if, and only if, the CDH problem is intractable. Protocol 1 and Protocol 2 guarantee the secrecy as in Definition 2 if, and only if, the DDH problem is intractable.

Fact 1 indicates that both Protocol 1 and Protocol 2 maintain a sound security promise when the CDH problem and the DDH problem are hard to solve.

### 3. Member Tampering Attacks on the Burmester-Desmedt Protocol

We know that any group  $U_1, U_2, \dots, U_t$  named as group  $A$  can execute a protocol run and negotiate a group session key  $K$  by using Equation (1) or Equation (3). We assume that members  $U_{i'}$  and  $U_{i''}$  are two malicious insiders in group  $A$ , that is,  $i', i'' \in \{1, 2, \dots, t\}$  and  $i' \neq i''$ . Without loss of generality, let  $0 < i' < i'' < t+1$ . Moreover, both members  $U_{i'}$  and  $U_{i''}$  simultaneously initiate an abnormal protocol run with another group  $U_{a_1}, U_{a_2}, \dots, U_{a_{t'}}$  named as the group  $B$ . Here,  $0 < a_j < n + 1$  for  $0 < j < t' + 1$ .

#### 3.1. Attacks on Broadcast Version

In the protocol run as shown in Figure 1, each member  $U_i$  ( $i = 1, 2, \dots, t$ ) of group  $A$  should compute and broadcast  $z_i = g^{r_i} \pmod p$  and  $X_i = (z_{i+1}/z_{i-1})^{r_i} \pmod p$  during Round 1 and Round 2 of Protocol 1. Finally, each member  $U_i$  ( $i = 1, 2, \dots, t$ ) is able to compute and share the same group session key  $K = g^{r_1 r_t + r_1 r_2 + r_2 r_3 + \dots + r_{t-2} r_{t-1} + r_{t-1} r_t} \pmod p$  by computing  $(z_{i-1})^{r_i} X_i^{t-1} X_{i+1}^{t-2} \dots X_{i-2} \pmod p$ . To realize the member tampering attack, two malicious insiders  $U_{i'}$  and  $U_{i''}$  of group  $A$  simultaneously start an abnormal protocol run with another group  $B$ . Let  $i'' - i' > 1$ . We assume that each member  $U_i$  ( $i = i' + 1, i' + 2, \dots, i'' - 1$ ) in the group  $A$  does not belong to the group  $B$ , that is,  $a_j \notin \{i'+1, i'+2, \dots, i'' - 1\}$  for all  $j \in \{1, 2, \dots, t'\}$ . After the abnormal protocol run of the group  $B$ , each member  $U_{a_j}$  ( $j = 1, 2, \dots, t'$ ) believes that not only members  $U_{a_j}$  ( $j = 1, 2, \dots, t'$ ) but also members  $U_i$  ( $i = i', i' + 1, \dots, i''$ ) take part in negotiating a group session key. However, all members  $U_i$  ( $i = i' + 1, i' + 2, \dots, i'' - 1$ ) in group  $A$  actually do not involve themselves in the abnormal protocol run of group  $B$ . In the following, we always write  $t' + i'' - i'$  as  $f$  to make the expression concise and easy to understand. We describe the abnormal protocol run as follows.

Round 1. Each member  $U_{a_j}$  ( $j = 1, 2, \dots, t'$ ) selects a random number  $r'_j \in Z_q$ , and computes and broadcasts  $z'_j = g^{r'_j} \pmod p$ . Each  $z_i$  generated by the member  $U_i$  ( $i = i', i'+1, \dots, i''$ ) also is broadcasted to group  $B$ .

Round 2. The malicious insider  $U_{i''}$  computes and broadcasts  $X'_{f+1} = (z'_1/z'_{i''-1})^{r'_{i''}}$  mod  $p$  and the member  $U_{a_1}$  computes and broadcasts  $X'_1 = (z'_2/z'_{i''})^{r'_{a_1}}$  mod  $p$ . Each member  $U_{a_j}$  ( $j = 2, \dots, t' - 1$ ) computes and broadcasts  $X'_j = (z'_{j+1}/z'_{j-1})^{r'_j}$  mod  $p$ . The member  $U_{a_{t'}}$  computes and broadcasts  $X'_{t'} = (z'_{t'}/z'_{t'-1})^{r'_{t'}}$  mod  $p$  and the malicious insider  $U_{i'}$  computes and broadcasts  $X'_{t'+1} = (z'_{i'-1}/z'_{t'})^{r'_{i'}}$  mod  $p$ . In addition, each  $X_i$  generated by the member  $U_i$  ( $i = i' + 1, \dots, i'' - 1$ ) is broadcasted to all members  $U_{a_j}$  ( $j = 1, 2, \dots, t'$ ).

Key Computation. Assume that  $r'_i = r_{i+i'-t'-1}$  and  $z'_i = z_{i+i'-t'-1}$ , where  $i = t' + 1, t' + 2, \dots, t' + i'' - i' + 1$  and  $X'_i = X_{i+i'-t'-1}$ , where  $i = t' + 2, t' + 3, \dots, f$ . Each member  $U_{a_j}$  ( $j = 1, 2, \dots, t'$ ) computes the group session key:

$$K'_j = (z'_{j-1})^{(f+1)r'_j} X'^f_{j+1} X'^{f-1}_{j+1} \dots X'_{j-2} \text{ mod } p, \tag{5}$$

where the indexes  $j$  in both  $z'_j$  and  $X'_j$  are performed modulo  $f + 1$ .

The member  $U_{i'}$  can share the group session key by calculating

$$K'_{i'} = (z'_{i'})^{(f+1)r'_{i'}} X'^f_{t'+1} X'^{f-1}_{t'+2} \dots X'_{t'-1} \text{ mod } p. \tag{6}$$

The member  $U_{i''}$  also can obtain the group session key by calculating

$$K'_{i''} = (z'_f)^{(f+1)r'_{i''}} X'^f_{f+1} X'^{f-1}_1 \dots X'_{f-1} \text{ mod } p. \tag{7}$$

According to Equation (5), we have

$$K'_j = (z'_{j-1})^{(f+1)r'_j} X'^f_{j+1} X'^{f-1}_{j+1} \dots X'_{j-2} \text{ mod } p = (z'_{j-1})^{(f+1)r'_j} \left(\frac{z'_{j+1}}{z'_{j-1}}\right)^{fr'_j} \left(\frac{z'_{j+2}}{z'_j}\right)^{(f-1)r'_{j+1}} \dots \left(\frac{z'_{j-1}}{z'_{j-3}}\right)^{r'_{j-2}} \text{ mod } p, \tag{8}$$

$$K'_j = (g^{r'_{j-1}})^{(f+1)r'_j} \left(\frac{g^{r'_{j+1}}}{g^{r'_{j-1}}}\right)^{fr'_j} \left(\frac{g^{r'_{j+2}}}{g^{r'_j}}\right)^{(f-1)r'_{j+1}} \dots \left(\frac{g^{r'_{j-1}}}{g^{r'_{j-3}}}\right)^{r'_{j-2}} \text{ mod } p \tag{9}$$

$$= (g^{r'_{j-1}})^{r'_j} (g^{r'_{j+1}})^{r'_j} (g^{r'_{j+2}})^{r'_{j+1}} \dots (g^{r'_{j-3}})^{r'_{j-2}} (g^{r'_{j-1}})^{r'_{j-2}} \text{ mod } p,$$

$$K'_j = g^{r'_1 r'_{f+1} + r'_1 r'_{f+1} + r'_1 r'_{f+1} + \dots + r'_{f-1} r'_f + r'_f r'_{f+1}} \text{ mod } p = g^{r'_1 r'_{i''} + r'_1 r'_{f+1} + r'_1 r'_{f+1} + \dots + r'_{i''-2} r'_{i''-1} + r'_{i''-1} r'_{i''}} \text{ mod } p. \tag{10}$$

Since  $r_{i'} = r'_{t'+1}$  and  $r_{i''} = r'_{f+1}$ , we know that Equations (6) and (7) satisfy Equation (5) when  $j = t' + 1$  and  $j = f + 1$ . Hence, all members  $U_{i'}, U_{a_j}$  ( $j = 1, 2, \dots, t'$ ),  $U_{i''}$  should share the same group session key  $K' = K'_{i'} = K'_{i''} = K'_j = g^{r'_1 r'_{i''} + r'_1 r'_{f+1} + r'_1 r'_{f+1} + \dots + r'_{i''-2} r'_{i''-1} + r'_{i''-1} r'_{i''}} \text{ mod } p$ . Moreover, all members  $U_{a_j}$  ( $j = 1, 2, \dots, t'$ ) believe that the members  $U_i$  ( $i = i' + 1, i' + 2, \dots, i'' - 1$ ) also exist in their group. Figure 3 shows member tampering attacks, which exploits two parallel protocol runs of group A and group B. In fact, the malicious insiders  $U_{i'}$  and  $U_{i''}$  also can use above attack to add the unknowing members  $U_i$  ( $i = 1, 2, \dots, i' - 1, i'' + 1, i'' + 2, \dots, t$ ) of the group A into the group B.

### 3.2. Attack on Cyclic Version

Consider the protocol run of group A. As shown in Figure 2, each member  $U_i$  ( $i = 1, 2, \dots, t$ ) computes  $z_i = g^{r_i} \text{ mod } p$  and sends it to the members  $U_{i-1}$  and  $U_{i+1}$  during Round 1 of Protocol 2. Each member  $U_i$  ( $i = 1, 2, \dots, t$ ) computes  $X_i = (z_{i+1}/z_{i-1})^{r_i} \text{ mod } p$ ,  $b_i = b_{i-1} X_i \text{ mod } p$ ,  $c_i = b_{i-1} c_{i-1} \text{ mod } p$ , where  $b_0 = c_0 = 1$ , and then sends  $b_i$  and  $c_i$  to the member  $U_{i+1}$  during Round 2 of Protocol 2. In Round 3 of Protocol 2, each member  $U_i$  ( $i = 1, 2, \dots, t - 1$ ) computes  $d_i = d d_{i-1} X_i^{-t} \text{ mod } p$ , where  $d = b_t$  and  $d_0 = c_t$ , and then sends  $d_i$  and  $d$  to the next member  $U_{i+1}$ . Finally, each member  $U_i$  ( $i = 1, 2, \dots, t$ ) computes and secretly shares the group session key  $K = K_i = (z_{i-1})^{t r_i} d_{i-1} \text{ mod } p$ .

Meanwhile, the malicious insiders  $U_{i'}$  and  $U_{i''}$  of group A also simultaneously start another abnormal protocol run with the group  $U_{a_1}, U_{a_2}, \dots, U_{a_{t'}}$ , i.e., group B. Here, we assume that  $i'' - i' < t - 1$  and  $a_j \notin \{1, 2, \dots, i' - 1, i'' + 1, i'' + 2, \dots, t\}$  for any  $j \in \{1, 2, \dots, t'\}$ . At the end of the abnormal protocol run of group B, each member  $U_{a_j}$  ( $j = 1, 2, \dots, t'$ ) mistakenly believes that the members  $U_i$ , where  $i = 1, 2, \dots, i' - 1, i'' + 1, i'' + 2, \dots, t$ , also are in their group and share a group session key with them, although any of these members

do not participate in in the abnormal protocol run. We assume that the malicious insider  $U_{i''}$  eavesdrops on all  $b_i$ , where  $i = 1, 2, \dots, i' - 2, i'' + 1, i'' + 2, \dots, t$ . Since the malicious insider  $U_{i''}$  knows  $b_0 = 1$ , he can further compute all  $X_i = b_i/b_{i-1} \bmod p$ , where  $i = 1, 2, \dots, i' - 1, i'' + 1, i'' + 2, \dots, t$ . Figure 4 depicts the member tampering attack on the cyclic version. For simplicity, we write  $t + i' + t' - i''$  as  $h$  in the following. We further describe the abnormal protocol run of group  $B$  as follows.

Round 1. The member  $U_{i'}$  sends  $z_{i'}$  to member  $U_{a_1}$ . The member  $U_{a_1}$  selects a random number  $r'_1 \in Z_q$ , computes  $z'_1 = g^{r'_1} \bmod p$  and sends  $z'_1$  to the members  $U_{i'}$  and  $U_{a_2}$ . Each member  $U_{a_j}$  ( $j = 2, 3, \dots, t' - 1$ ) selects a random number  $r'_j \in Z_q$ , computes  $z'_j = g^{r'_j} \bmod p$ , and sends  $z'_j$  to the members  $U_{a_{j-1}}$  and  $U_{a_{j+1}}$ . The member  $U_{a_{t'}}$  selects a random number  $r'_{t'} \in Z_q$  and computes  $z'_{t'} = g^{r'_{t'}} \bmod p$ , and then sends  $z'_{t'}$  to the members  $U_{a_{t'-1}}$  and  $U_{i''}$ . The member  $U_{i''}$  sends his  $z_{i''}$  to the member  $U_{a_{t'}}$ .

Round 2. The member  $U_{i'}$  computes and updates his new  $X'_{h+1} = (z'_1/z_{i'-1})^{r'_{t'}}$  mod  $p$ . The member  $U_{i'}$  then computes  $b' = b_{i'-1}X'_{h+1} \bmod p$  and  $c' = c_{i'} = b_{i'-1}c_{i'-1} \bmod p$ , and further sends  $b'$  and  $c'$  to the member  $U_{a_1}$ . The member  $U_{a_1}$  computes  $X'_1 = (z'_2/z_{i'})^{r'_1} \bmod p$ . Moreover, member  $U_{a_1}$  computes  $b'_1 = b'X'_1 \bmod p$  and  $c'_1 = b'c' \bmod p$ , and then sends  $b'_1$  and  $c'_1$  to the next member  $U_{a_2}$ . Each member  $U_{a_j}$  ( $j = 2, 3, \dots, t' - 1$ ) computes  $X'_j = (z'_{j+1}/z'_{j-1})^{r'_j} \bmod p$ . For  $j = 2$  to  $t' - 1$ , the member  $U_{a_j}$  computes  $b'_j = b'_{j-1}X'_j \bmod p$  and  $c'_j = b'_{j-1}c'_{j-1} \bmod p$ , and then sends  $b'_j$  and  $c'_j$  to  $U_{a_{j+1}}$ . Upon receiving the member  $U_{a_{t'-1}}$ 's  $b'_{t'-1}$  and  $c'_{t'-1}$ , the member  $U_{a_{t'}}$  computes  $X'_{t'} = (z_{i''}/z'_{t'-1})^{r'_{t'}}$  mod  $p$ ,  $b'_{t'} = b'_{t'-1}X'_{t'} \bmod p$ ,  $c'_{t'} = b'_{t'-1}c'_{t'-1} \bmod p$ , and then sends  $b'_{t'}$  and  $c'_{t'}$  to the member  $U_{i''}$ . Upon receiving the member  $U_{a_{t'}}$ 's  $b'_{t'}$  and  $c'_{t'}$ , the member  $U_{i''}$  calculates his  $X'_{t'+1} = (z_{i''-1}/z'_{t'})^{r'_{t'}}$  mod  $p$ ,  $b'_{t'+1} = b'_{t'}X'_{t'+1} \bmod p$ ,  $c'_{t'+1} = b'_{t'}c'_{t'}$  mod  $p$ . For  $i = i'' + 1$  to  $t$ , the member  $U_{i''}$  further computes  $b'_{i+t'-i''+1} = b'_{i+t'-i''}X_i \bmod p$  and  $c'_{i+t'-i''+1} = b'_{i+t'-i''}c'_{i+t'-i''} \bmod p$ .

Round 3. Let  $d'_0 = c'_{t+t'-i''+1}$ . For  $i = 1$  to  $i' - 1$ , the member  $U_{i''}$  computes  $d'_i = b'_{t+t'-i''+1}d'_{i-1}X_i^{-(h+1)} \bmod p$ . And then, the member  $U_{i''}$  sends  $d'_{i'-1}$  and  $b'_{t+t'-i''+1}$  to the member  $U_{i'}$ . The member  $U_{i'}$  computes  $d'_{i'} = b'_{t+t'-i''+1}d'_{i'-1}X'_{h+1}^{-(h+1)} \bmod p$  and sends  $d'_{i'}$  and  $b'_{t+t'-i''+1}$  to the member  $U_{a_1}$ . For  $j = 1$  to  $t' - 1$ , the member  $U_{a_j}$  computes  $d'_{j+i'} = b'_{t+t'-i''+1}d'_{j+i'-1}X'_j^{-(h+1)} \bmod p$ , and then sends  $d'_{j+i'}$  and  $b'_{t+t'-i''+1}$  to the member  $U_{a_{j+1}}$ . Upon receiving the member  $U_{a_{j-1}}$ 's  $d'_{j+i'-1}$  and  $b'_{t+t'-i''+1}$ , the member  $U_{a_j}$  computes  $d'_{j+i'} = b'_{t+t'-i''+1}d'_{j+i'-1}X'_j^{-(h+1)} \bmod p$ , and then sends  $d'_{j+i'}$  and  $b'_{t+t'-i''+1}$  to the member  $U_{i''}$ .

Key Computation. Let  $z'_0 = z_{i'}$ . Each member  $U_{a_j}$  ( $j = 1, 2, \dots, t'$ ) computes the group session key:

$$Kt_j = (z_{t_{j-1}})^{(h+1)r'_j} d'_{j+i'-1} \bmod p. \tag{11}$$

The member  $U_{i'}$  shares the group session key by calculating

$$K'_{i'} = (z_{i'-1})^{(h+1)r'_{i'}} d'_{i'-1} \bmod p. \tag{12}$$

The member  $U_{i''}$  also obtains the group session key by computing

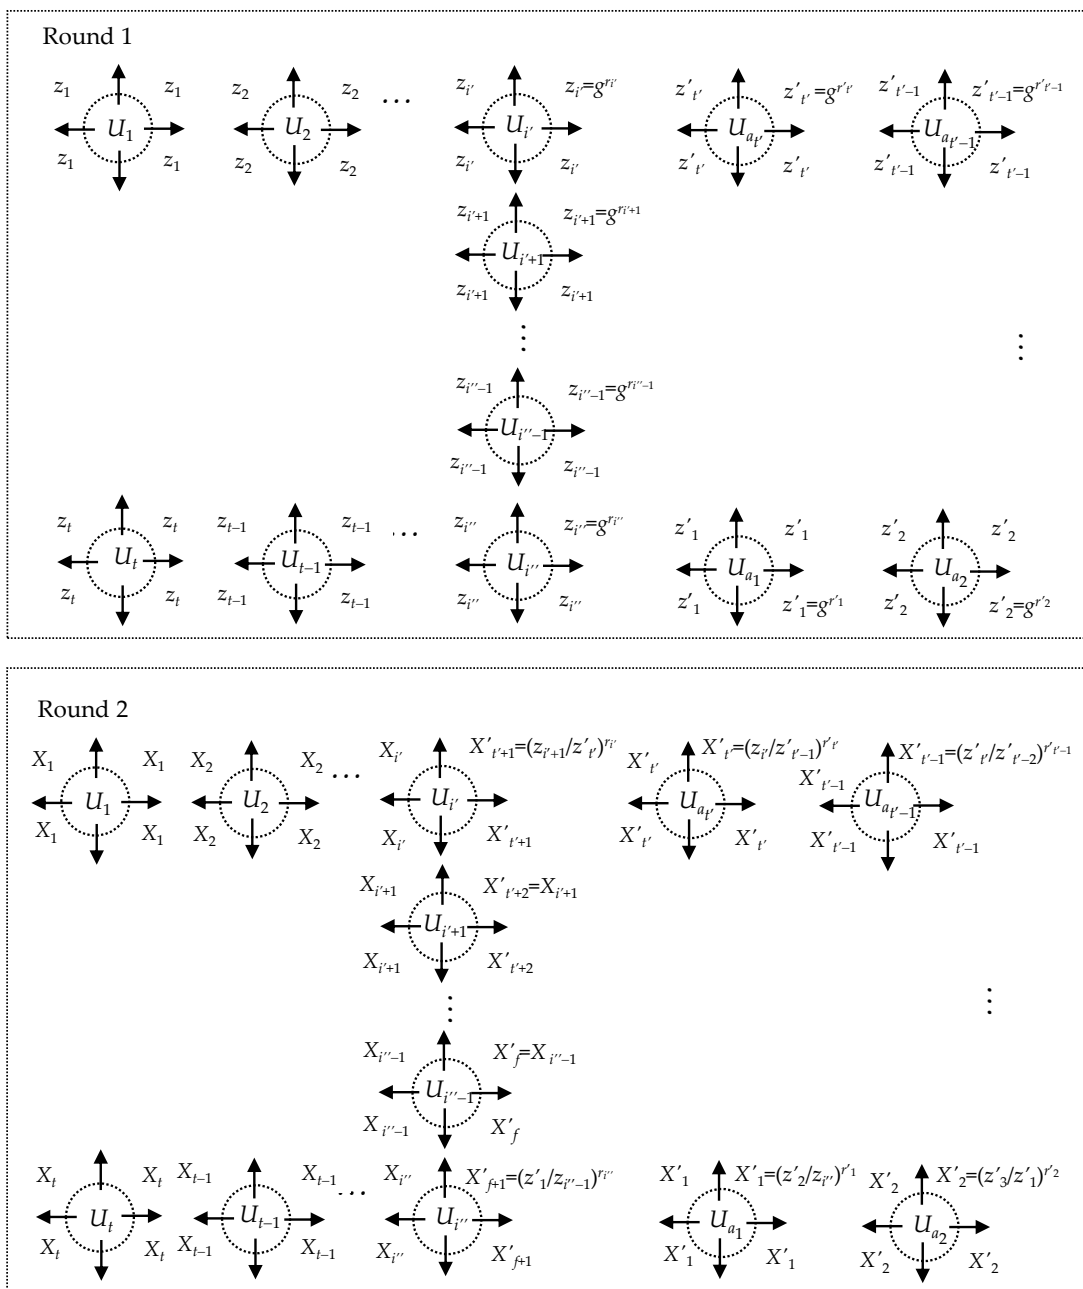

$$K'_{i''} = (z'_{t'})^{(h+1)r'_{i''}} d'_{i'+t'} \bmod p. \tag{13}$$

In the following, we analyze and confirm the group session key shared among the members  $U_{i'}$ ,  $U_{a_j}$  ( $j = 1, 2, \dots, t'$ ),  $U_{i''}$ . During Round 1, the members  $U_{i'}$  and  $U_{i''}$  reuse their  $z_{i'}$  and  $z_{i''}$  generated in the protocol run of the group  $A$  and send  $z_{i'}$  to the member  $U_{a_1}$  and  $z_{i''}$  to the member  $U_{a_{t'}}$ . During Round 2, the member  $U_{i'}$  computes his new  $X'_{h+1} = (z'_1/z_{i'-1})^{r'_{t'}}$  mod  $p$  instead of the old  $X_{i'} = (z_{i'+1}/z_{i'-1})^{r'_{t'}}$  mod  $p$  in the protocol run of the group  $A$ , and uses this  $X'_{h+1}$  to compute  $b' = b_{i'-1}X'_{h+1} \bmod p$ . Then, the member  $U_{a_1}$  computes  $X'_1 = (z'_2/z_{i'})^{r'_1} \bmod p$  and  $b'_1 = b'X'_1 \bmod p$  and the member  $U_{a_j}$  computes  $X'_j = (z'_{j+1}/z'_{j-1})^{r'_j} \bmod p$  and  $b'_j = b'_{j-1}X'_j \bmod p$  for  $j = 2$  to  $t'$ . After calculating  $X'_{t'+1} = (z_{i''-1}/z'_{t'})^{r'_{t'}}$  mod  $p$  and  $b'_{t'+1} = b'_{t'}X'_{t'+1} \bmod p$ , the member  $U_{i''}$  can sequentially compute each member  $U_i$ 's  $b'_{i+t'-i''+1} = b'_{i+t'-i''}X_i \bmod p$ , where  $i = i'' + 1, i'' + 2, \dots, t$ . The

reason is that the member  $U_{i''}$  had eavesdropped on all  $b_i$  for  $i = i'' + 1, i'' + 2, \dots, t$  in the protocol run of the group  $A$  and can derive the member  $U_i$ 's  $X_i$  by computing  $b_i/b_{i-1} \pmod p$ . Therefore, we know that

$$b' = b_{i'-1}X'_{h+1} = X_1X_2 \dots X_{i'-1}X'_{h+1} \pmod p, \tag{14}$$

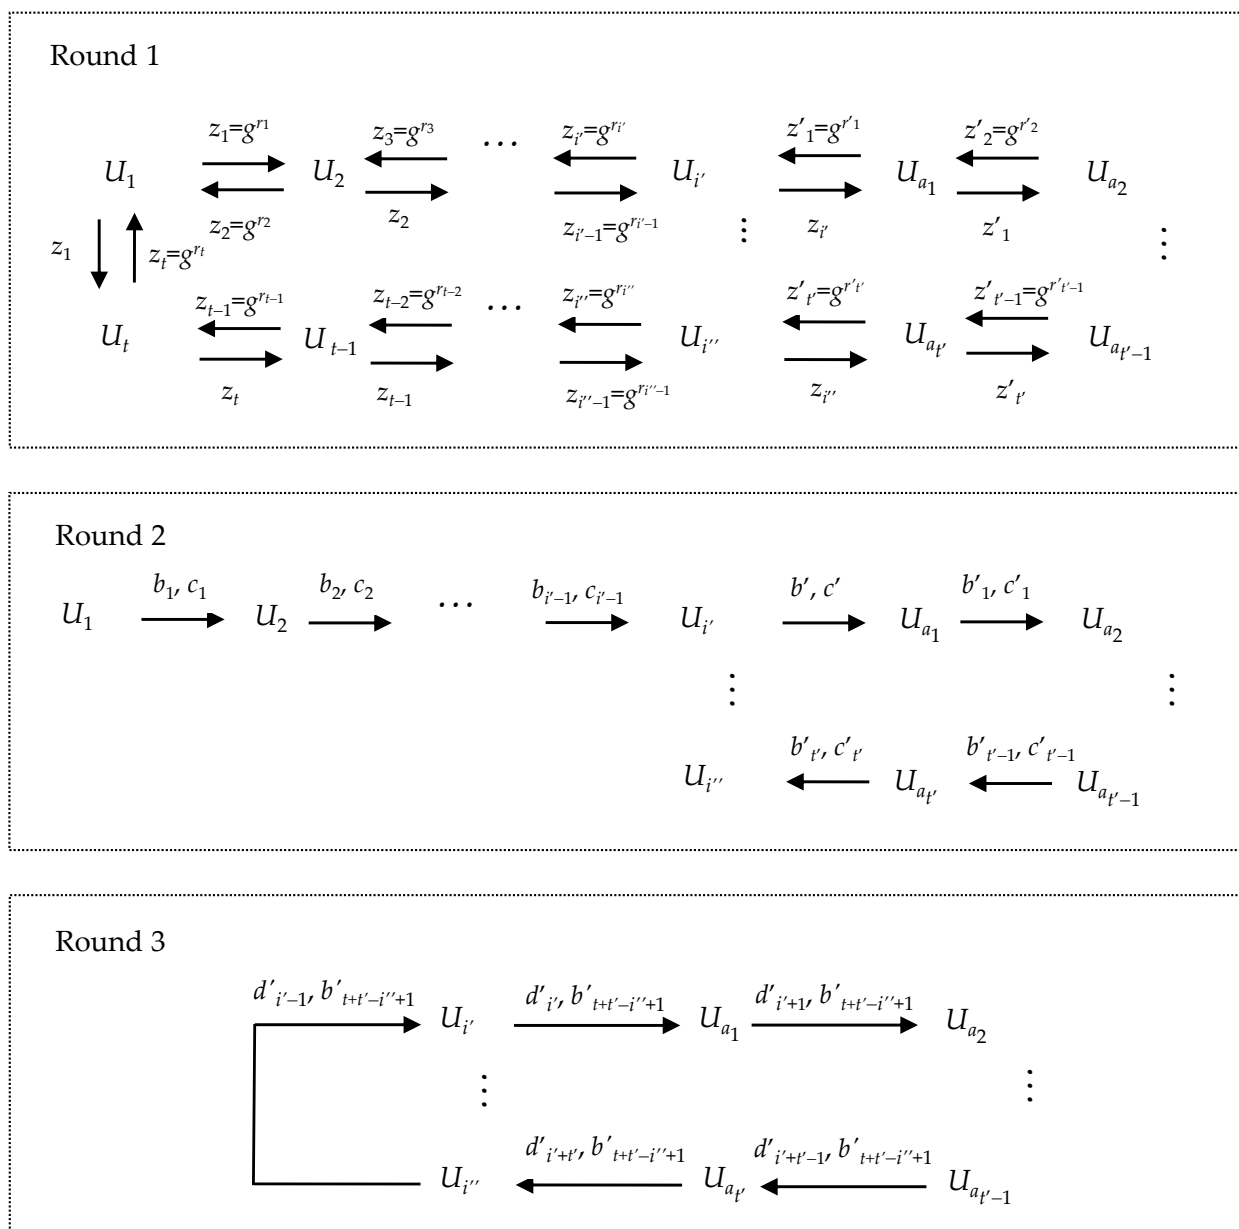

$$\begin{aligned} b_{i'} &= b_{i'-1}X'_{i'} = b_{i'-2}X'_{i'-1}X'_{i'} = b'X'_{i-1} \dots X'_{i'-1}X'_{i'} \\ &= X_1X_2 \dots X_{i'-1}X'_{h+1}X'_1 \dots X'_{i'-1}X'_{i'} \pmod p, \end{aligned} \tag{15}$$

Shared session key among  $U_{i''}, U_{a1}, \dots, U_{a_{i'-1}}, U_{i'}$ :

$$K' = g^{r'_{i''}r'_{i''+1} + r'_{i''}r'_{i''+2} + r'_{i''}r'_{i''+3} + \dots + r'_{i''-1}r'_{i''} + r'_{i''-1}r'_{i''+1} + r'_{i''-1}r'_{i''+2} + \dots + r'_{i''-2}r'_{i''-1} + r'_{i''-1}r'_{i''}} \pmod p$$

Figure 3. Member tampering attack on the broadcast protocol.

Shared session key among  $U_{i'}, U_{a_1}, \dots, U_{a'_{p-1}}, U_{i''}$ :  
 $K' = g^{r_1 r_2 + r_2 r_3 + \dots + r_{i'} r_1 + r_1 r'_2 + \dots + r'_{i''} r_1 + r_1 r_{i''+1} + \dots + r_t r_1} \text{ mod } p$

Figure 4. Member tampering attack on the cyclic protocol.

and

$$\begin{aligned}
 b'_{t+t'-i''+1} &= b'_{t+t'-i''} X_t = b'_{t+t'-i''-1} X_{t-1} = \dots = \\
 b'_{i'+1} X_{i''+1} X_{i''+2} \dots X_{t-1} X_t &= b'_{i'} X'_{i'+1} X_{i''+1} X_{i''+2} \dots X_{t-1} X_t = \\
 X_1 X_2 \dots X_{i'-1} X'_{h+1} X'_1 \dots X'_{i'-1} X'_{i'} X'_{i'+1} X_{i''+1} X_{i''+2} \dots X_{t-1} X_t \text{ mod } p.
 \end{aligned}
 \tag{16}$$

According to the analysis in Section 2.2, we have  $c' = c_{i'} = b_{i'-1} c_{i'-1} = X_1 X_2 \dots X_{i'-2} X_{i'-1} X_1^{i'-2} X_2^{i'-3} \dots X_{i'-2} = X_1^{i'-1} X_2^{i'-2} \dots X_{i'-2}^2 X_{i'-1} \text{ mod } p$ . Since  $b' = b_{i'-1} X'_{h+1} \text{ mod } p$  in Round 2 of the group  $B$ ,  $c'_1 = b' c' = b_{i'-1} X'_{h+1} c' = b_{i'-1} X'_{h+1} X_1^{i'-1} X_2^{i'-2} \dots X_{i'-2}^2 X_{i'-1} = X_1 X_2 \dots X_{i'-2} X_{i'-1} X'_{h+1} X_1^{i'-1} X_2^{i'-2} \dots X_{i'-2}^2 X_{i'-1} = X_1^{i'} X_2^{i'-1} \dots$

$X_{t'-2}^3 X_{t'-1}^2 X'_{h+1} \pmod p$ . We further get  $c'_j = b'_{j-1} c'_{j-1} = b'_{j-1} b'_{j-2} c'_{j-2} = \dots = b'_{j-1} b'_{j-2} \dots b'_1 c'_1 \pmod p$  for  $j = 2$  to  $t'$ . Therefore,

$$\begin{aligned} c'_{t'} &= b'_{t'-1} b'_{t'-2} \dots b'_1 c'_1 = X'_{t'-1} b'_{t'-2} b'_{t'-3} \dots b'_1 c'_1 = \dots \\ &= X'_{t'-1} X_{t'-2}^2 \dots X_2^{t'-2} b_1^{t'-1} c'_1 = X'_{t'-1} X_{t'-2}^2 \dots X_2^{t'-2} X_1^{t'-1} b_1^{t'-1} c'_1 \\ &= X'_{t'-1} X_{t'-2}^2 \dots X_2^{t'-2} X_1^{t'-1} X_1^{t'-1} X_2^{t'-1} \dots X_{t'-1}^{t'-1} X_{h+1}^t X_1^t X_2^{t-1} \dots X_{t'-1}^2 X'_{h+1} \pmod p, \end{aligned} \tag{17}$$

$$c'_{t'} = X'_{t'-1} X_{t'-2}^2 \dots X_2^{t'-2} X_1^{t'-1} X'_{h+1} X_{t'-1}^{t'+1} \dots X_2^{t'+i'-2} X_1^{t'+i'-1} \pmod p. \tag{18}$$

Since the member  $U_{i''}$  in Round 2 of the group  $B$  computes  $b'_{t'+1} = b'_{t'} X'_{t'+1} \pmod p$  and  $c'_{t'+1} = b'_{t'} c'_{t'} \pmod p$ , and then calculates  $b'_{i+t'-i''+1} = b'_{i+t'-i''} X_i \pmod p$  and  $c'_{i+t'-i''+1} = b'_{i+t'-i''} c'_{i+t'-i''} \pmod p$  for  $i = i'' + 1$  to  $t$ , we have

$$\begin{aligned} c'_{t+t'-i''+1} &= b'_{t+t'-i''} c'_{t+t'-i''} = b'_{t+t'-i''} b'_{t+t'-i''-1} c'_{t+t'-i''-1} = \dots = \\ &= b'_{t+t'-i''} b'_{t+t'-i''-1} \dots b'_{t'+1} c'_{t'+1} = b'_{t+t'-i''} b'_{t+t'-i''-1} \dots b'_{t'+1} b'_{t'} c'_{t'}, \end{aligned} \tag{19}$$

$$\begin{aligned} c'_{t+t'-i''+1} &= X_{t-1} X_{t-2}^2 \dots X_{t'+1}^{t-i''-1} X_{t'+1}^{t-i''} b_1^{t-i''+1} c'_{t'} \\ &= X_{t-1} X_{t-2}^2 \dots X_{t'+1}^{t-i''-1} X_{t'+1}^{t-i''} X_1^{t-i''+1} X_2^{t-i''+1} \dots \\ &X_{t'-1}^{t-i''+1} X_{h+1}^{t-i''+1} X_1^{t-i''+1} X_2^{t-i''+1} \dots X_{t'-2}^{t-i''+1} X_{t'-1}^{t-i''+1} X_{t'-1}^{t-i''+1} X_{t'-1} \\ &X_{t'-2}^2 \dots X_2^{t'-2} X_1^{t'-1} X_{h+1} X_{t'-1} \dots X_2^{t'+i'-2} X_1^{t'+i'-1} \pmod p, \end{aligned} \tag{20}$$

$$\begin{aligned} c'_{t+t'-i''+1} &= X_1^h X_2^{h-1} \dots X_{t'-1}^{t+i'-i''+2} X_{h+1}^{t+i'-i''+1} X_1^{t+i'-i''} X_2^{t+i'-i''-1} \\ &\dots X_{t'-2}^{t-i''+3} X_{t'-1}^{t-i''+2} X_{t'}^{t-i''+1} X_{t'+1}^{t-i''} X_{t'+1}^{t-i''-1} \dots X_{t-2}^2 X_{t-1} \pmod p. \end{aligned} \tag{21}$$

In Round 3 of the group  $B$ , we know  $d'_0 = c'_{t+t'-i''+1}$  and  $d'_i = b'_{t+t'-i''+1} d'_{i-1} X_i^{-(h+1)} \pmod p$  or  $i = 1$  to  $i' - 1$ . That is,  $d'_{i-1} = b'_{t+t'-i''+1} d'_{i-2} X_{i-1}^{-(h+1)} = b'_{t+t'-i''+1} d'_{i-3} X_{i-1}^2 X_{i-2}^{-(h+1)} X_{i-2}^{-(h+1)}$   $= \dots = b'_{t+t'-i''+1} X_{i-1}^{i'-1} X_{i-1}^{-(h+1)} X_{i-2}^{-(h+1)} \dots X_1^{-(h+1)} d'_0 = b'_{t+t'-i''+1} X_{i-1}^{i'-1} X_{i-1}^{-(h+1)} X_{i-2}^{-(h+1)}$   $\dots X_2^{-(h+1)} X_1^{-(h+1)} c'_{t+t'-i''+1} \pmod p$ . Now we have

$$\begin{aligned} d'_{i-1} &= b_{t+t'-i''+1}^{i'-1} X_{i-1}^{-(h+1)} X_{i-2}^{-(h+1)} \dots X_2^{-(h+1)} X_1^{-(h+1)} c'_{t+t'-i''-1} = \\ &(X_1 X_2 \dots X_{i-2} X_{i-1} X'_{h+1} X_1 X_2 \dots X_{t'-2} X_{t'-1} X_{t'} X_{t'+1} X_{t'+1} \dots X_{t-2} X_{t-1} X_t)^{i'-1} \\ &X_{i-1}^{-(h+1)} X_{i-2}^{-(h+1)} \dots X_2^{-(h+1)} X_1^{-(h+1)} X_1^h X_2^{h-1} \dots X_2^{t+i'-i''-1} \dots X_{t'-2}^{t-i''+3} X_{t'-1}^{t-i''+2} \\ &X_{t'}^{t-i''+1} X_{t'+1}^{t-i''} X_{t'+1}^{t-i''-1} \dots X_{t-2}^2 X_{t-1} \pmod p, \end{aligned} \tag{22}$$

$$\begin{aligned} d'_{i-1} &= X_{h+1}^h X_1^{h-1} X_2^{h-2} \dots X_{t'-2}^{t+i'-i''+2} X_{t'-1}^{t+i'-i''+1} X_{t'}^{t+i'-i''} \\ &X_{t'+1}^{t+i'-i''-1} X_{t'+1}^{t+i'-i''-2} \dots X_{t-2}^{i'+1} X_{t-1}^{i'} X_t^{i'-1} X_1^{i'-2} X_2^{i'-3} \dots X_{i-2} \pmod p. \end{aligned} \tag{23}$$

Owing to  $d'_{i'} = b'_{t+t'-i''+1} d'_{i'-1} X'_{h+1}^{-(h+1)} \pmod p$ , we get

$$\begin{aligned} d'_{i'} &= X_1 X_2 \dots X_{i'-2} X_{i'-1} X'_{h+1} X_1 X_2 \dots X_{t'-2} X_{t'-1} X_{t'} X_{t'+1} X_{t'+1} \dots \\ &X_{t-2} X_{t-1} X_t X_{h+1}^h X_1^{h-1} X_2^{h-2} \dots X_{t'-2}^{t+i'-i''+2} X_{t'-1}^{t+i'-i''+1} X_{t'}^{t+i'-i''} \\ &X_{t'+1}^{t+i'-i''-1} X_{t'+1}^{t+i'-i''-2} \dots X_{t-2}^{i'+1} X_{t-1}^{i'} X_t^{i'-1} X_1^{i'-2} X_2^{i'-3} \dots X_{i'-2} X_{h+1}^{-(h+1)} \pmod p, \end{aligned} \tag{24}$$

$$\begin{aligned} d'_{i'} &= X_1^h X_2^{h-1} \dots X_{t'-2}^{t+i'-i''+3} X_{t'-1}^{t+i'-i''+2} X_{t'}^{t+i'-i''+1} X_{t'+1}^{t+i'-i''} X_{t'+1}^{t+i'-i''-1} \\ &\dots X_{t-2}^{i'+2} X_{t-1}^{i'+1} X_t^{i'} X_1^{i'-1} X_2^{i'-2} \dots X_{i'-2}^2 X_{i'-1} \pmod p. \end{aligned} \tag{25}$$

Since  $d'_{j+i'} = b'_{t+t'-i''+1} d'_{j+i'-1} X_j^{-(h+1)} \pmod p$  for  $j = 1$  to  $t' - 1$  and  $d'_{t+i'} = b'_{t+t'-i''+1} d'_{t+i'-1} X_t^{-(h+1)} \pmod p$ , we get

$$\begin{aligned} d'_{j+i'} &= b_{t+i'-i''+1}^{t'} d'_{j+i'-2} X_j^{-(h+1)} = \dots = b_{t+i'-i''+1}^{t'} d'_{i'} X_j^{-(h+1)} \\ &X_{j-1}^{-(h+1)} X_{j-2}^{-(h+1)} \dots X_1^{-(h+1)} \pmod p, \end{aligned} \tag{26}$$

$$\begin{aligned}
 & d'_{j+i'} \\
 &= (X_1 X_2 \dots X_{i'-1} X'_{h+1} X'_1 \dots X'_{j-2} X'_{j-1} X'_j X'_{j+1} X'_{j+2} \dots X'_{t'} X'_{t'+1} X_{i''+1} \dots X_{t-2} X_{t-1} X_t)^j \\
 & X_1^h \dots X_{j-2}^{h-j+3} X_{j-1}^{h-j+2} X_j^{h-j+1} X_{j+1}^{h-j} X_{j+2}^{h-j-1} \dots X_{t'}^{t+i'-i''+1} X_{t'+1}^{t+i'-i''} X_{t'+2}^{t+i'-i''-1} \dots \\
 & X_{t-2}^{i'+2} X_{t-1}^{i'+1} X_t^{i'} X_1^{i'-1} X_2^{i'-2} \dots X_{i'-1} X_j^{-(h+1)} X_{j-1}^{-(h+1)} X_{j-2}^{-(h+1)} \dots X_1^{-(h+1)} \pmod p,
 \end{aligned} \tag{27}$$

$$\begin{aligned}
 & d'_{j+i'} = X_{j+1}^h X_{j+2}^{h-1} \dots X_{t'}^{j+t+i'-i''+1} X_{t'+1}^{j+t+i'-i''} X_{t'+2}^{j+t+i'-i''-1} \dots \\

 \end{aligned} \tag{30}$$

Let  $X'_{l+t+i'-i''+1} = X_l \pmod p$  for  $l = 1$  to  $i' - 1$  and  $X'_{l+t'-i''+1} = X_l \pmod p$  for  $l = i'' + 1$  to  $t$ . Moreover, let  $n' = h + 1$  and any index  $j$  but  $X'_i$  and  $X'_j$  are the same value when satisfying  $i = j \pmod{n'}$ . According to Equations (11), (25), and (28), we have

$$\begin{aligned}
 & K'_j = (z'_{j-1})^{(h+1)r'_j} d'_{j+i'-1} \\
 & = (z'_{j-1})^{(h+1)r'_j} X_{j+1}^h X_{j+2}^{h-1} \dots X_{t'}^{j+t+i'-i''+1} X_{t'+1}^{j+t+i'-i''} \\
 & X_{t'+2}^{j+t+i'-i''-1} \dots X_{t+t'-i''-1}^{j+i'+2} X_{t+t'-i''}^{j+i'+1} X_{t+t'-i''+1}^{j+i'} X_{t+t'-i''+2}^{j+i'-1} X_{t+t'-i''+3}^{j+i'-2} \dots \\
 & X_h^{j+1} X_{h+1}^j X_1^{j-1} \dots X_{j-2}^2 X_{j-1} \pmod p
 \end{aligned} \tag{31}$$

for  $j = 1, 2, \dots, t'$ . We write  $z'_h = z'_{i'-1}, r'_{h+1} = r'_{i'}, r'_{t'+1} = r'_{i''}$ . By Equations (23) and (30), and Equations (12) and (13) become

$$\begin{aligned}
 & K'_{i'} = (z'_{i'-1})^{(h+1)r'_{i'}} d'_{i'-1} = (z'_h)^{(h+1)r'_{h+1}} X_{h+1}^h X_1^{h-1} X_2^{h-2} \dots \\
 & X_{t'-2}^{t+i'-i''+2} X_{t'-1}^{t+i'-i''+1} X_{t'}^{t+i'-i''} X_{t'+1}^{t+i'-i''-1} X_{t'+2}^{t+i'-i''-2} \dots X_{t+t'-i''-1}^{i'+1} \\
 & X_{t+t'-i''}^{i'} X_{t+t'-i''+1}^{i'-1} X_{t+t'-i''+2}^{i'-2} X_{t+t'-i''+3}^{i'-3} \dots X_{h-1} \pmod p
 \end{aligned} \tag{32}$$

and

$$\begin{aligned}
 & K'_{i''} = (z'_{t'})^{(h+1)r'_{i''}} d'_{t'+t'} = (z'_{t'})^{(h+1)r'_{t'+1}} X_{t'+1}^h X_{t'+2}^{h-1} \dots X_{t+t'-i''+2}^{i'+t'+2} X_{t+t'-i''-1}^{i'+t'+1} \\
 & X_{t+t'-i''+1}^{i'+t'} X_{t+t'-i''+2}^{i'+t'-1} X_{t+t'-i''+3}^{i'+t'-2} \dots X_h^{t'+1} X_{h+1}^{t'} X_1^{t'-1} \dots X_{t'-3}^3 X_{t'-2}^2 X_{t'-1} \pmod p.
 \end{aligned} \tag{33}$$

According to Equations (31)–(33), we know Equations (11)–(13) are strictly consistent with Equation (1). This means that  $h+1$  members, i.e., the members  $U_{a_j}$  ( $j = 1, 2, \dots, t'$ ) and  $U_i$  ( $i = 1, 2, \dots, i', i'', i'' + 1, \dots, t$ ), run cyclic version of the protocol. Finally, we can concluded that each member  $U_{a_j}$  ( $j = 1, 2, \dots, t'$ ) believes the members  $U_i$  ( $i = 1, 2, \dots, i', i'', i'' + 1, \dots, t$ ) of group  $A$  are in their group and share the secret key, i.e.,  $K' = g^{r_1 r_2 + r_2 r_3 + \dots + r_{i'} r_1 + r'_1 r'_2 + \dots + r'_{i'} r_{i''} + r_{i''} r_{i''+1} + \dots + r_t r_1} \pmod p$ . However, the fact is that the members  $U_i$  ( $i = 1, 2, \dots, i' - 1, i'' + 1, i'' + 2, \dots, t$ ) do not take part in the abnormal protocol run with the group  $B$ . It needs to point out that the member  $U_{i''}$  can select the part of the members  $U_i$  ( $i = i'' + 1, i'' + 2, \dots, t$ ) to add in the group  $B$  or ignore them all. Assume that  $S \subset \{i'' + 1, i'' + 2, \dots, t\}$  and the member  $U_{i''}$  wants to include the members  $U_{i \in S}$  into group  $B$ . The member  $U_{i''}$  only modifies the computation of the  $b'_{i+t'-i''+1}$  and  $c'_{i+t'-i''+1}$  in

Round 2. That is, for  $i = i'' + 1$  to  $t$ , the member  $U_{i''}$  computes  $b'_{i+t'-i''+1} = b'_{i+t'-i''} X_i \text{ mod } p$  and  $c'_{i+t'-i''+1} = b'_{i+t'-i''} c'_{i+t'-i''} \text{ mod } p$ , when  $i \in S$ .

*Further comment.* The member tampering attacks are possibly exploited to cheat the members of the group and threaten group communication security. One threat scenario is patient consultation in telemedicine. When the medical experts and the patient establish a group communication by using the Burmester-Desmedt protocol, two medical experts can add some experts who have not participated in the consultation to the group as needed. This behavior can improve the authority of the consultation. Another threat scenario is the online auction system. If the online auction system runs the Burmester-Desmedt protocol, two members in the auction group can include the auction notaries, who do not exist in the auction group.

#### 4. Countermeasure and Open Problem

The reason why the Burmester-Desmedt protocol suffers is that the members have not explicitly verified the identity of other members in the group. Therefore, the malicious insiders in the group can reuse messages of another protocol run to cheat other members into believing the non-existent members. If each member can confirm the identity of other members in the group during the protocol run, it is difficult for malicious insiders to add those dummy members.

Let  $\text{Sign}_{sk_{U_i}}()$  and  $\text{Vrfy}_{pk_{U_i}}()$  ( $i = 1, 2, \dots, n$ ) denote the member  $U_i$ 's signature function using private key  $sk_{U_i}$  and verification function using public key  $pk_{U_i}$ . We require the signature scheme that is existentially unforgeable under an adaptive chosen-message attack. Here, the existentially unforgeable property and the game of adaptive chosen-message attack are the standard notions of security for digital signature schemes. Let  $U_i$  ( $i = 1, 2, \dots, n$ ) be the member  $U_i$ 's recognizable identities (in lexicographic order) wishing to establish the group session key. Let  $\parallel$  be the concatenation operator. In the following, we provide the improvements on the Burmester-Desmedt protocol to defeat the member tampering attack.

In broadcast version as Figure 1, we require each member  $U_i$  ( $i = 1, 2, \dots, t$ ) to receiving all  $z_j$  and  $X_j$  during Round 1 and Round 2, where  $j = 1, 2, \dots, t$  and  $j \neq i$ . More importantly, each member  $U_i$  simultaneously computes and broadcasts  $S_i = \text{Sign}_{sk_{U_i}}(z_1 \parallel X_1 \parallel U_{I_1} \parallel z_2 \parallel X_2 \parallel U_{I_2} \parallel \dots \parallel z_t \parallel X_t \parallel U_{I_t})$  in Round 2. Moreover, upon receiving all messages from other members, each member  $U_i$  also should verify all  $S_j$  by computing  $\text{Vrfy}_{pk_{U_i}}(S_j)$ , where  $j = 1, 2, \dots, t$  and  $j \neq i$ . If any verification operation fails, the member  $U_i$  should terminate the protocol run. When an adversary wants to illegally include any member  $U_j$  into a certain group and cheat other members of the group, he must forge the member  $U_j$ 's signature  $S_j$  during the protocol run. This signature signs recognizable identities of all group members and the fresh random values generated by all group members. However, the security of the signature algorithm [28] prevents the possibility of forging the member  $U_j$ 's signature without his private key  $sk_{U_i}$ .

In cyclic version as Figure 2, we assume that each member  $U_i$  ( $i = 1, 2, \dots, t$ ) knows all other members  $U_j$ , where  $j = 1, 2, \dots, t$  and  $j \neq i$ , potentially are in the group before the protocol run starts. Figure 5 shows our improvement of cyclic version. Our Round 1 and Round 2 are fully same as cyclic version described in Figure 2. During Round 3, we require each member  $U_i$  ( $i = 1, 2, \dots, t$ ) simultaneously computes the signature  $SC_i = \text{Sign}_{sk_{U_i}}(K_i \parallel U_{I_1} \parallel U_{I_2} \parallel \dots \parallel U_{I_t})$ , and then each member  $U_i$  ( $i = 1, 2, \dots, t - 1$ ) sends the signatures  $SC_1, SC_2, \dots, SC_i$  to the next member  $U_{i+1}$  and the member  $U_t$  sends the signatures  $SC_2, SC_3, \dots, SC_t$  to the member  $U_1$ . After Round 3, we additionally demand a new round named Round 4. In Round 4, each member  $U_i$  ( $i = 1, 2, \dots, t - 2$ ) sends the signatures  $SC_{i+2}, SC_{i+3}, \dots, SC_t$  to the member  $U_{i+1}$ . In Round 3 and Round 4, each member  $U_i$  ( $i = 1, 2, \dots, t$ ) should verify all signatures  $SC_j$  by computing  $\text{Vrfy}_{pk_{U_i}}(SC_j)$ , where  $j = 1, 2, \dots, t$  and  $j \neq i$ . If any verification operation fails, the member  $U_i$  should immediately terminate the protocol run. For reasons similar to the improved broadcast version, the

improved cyclic version also can resist the member tampering attack under the malicious active insider or outsider, when the signature algorithm is secure.

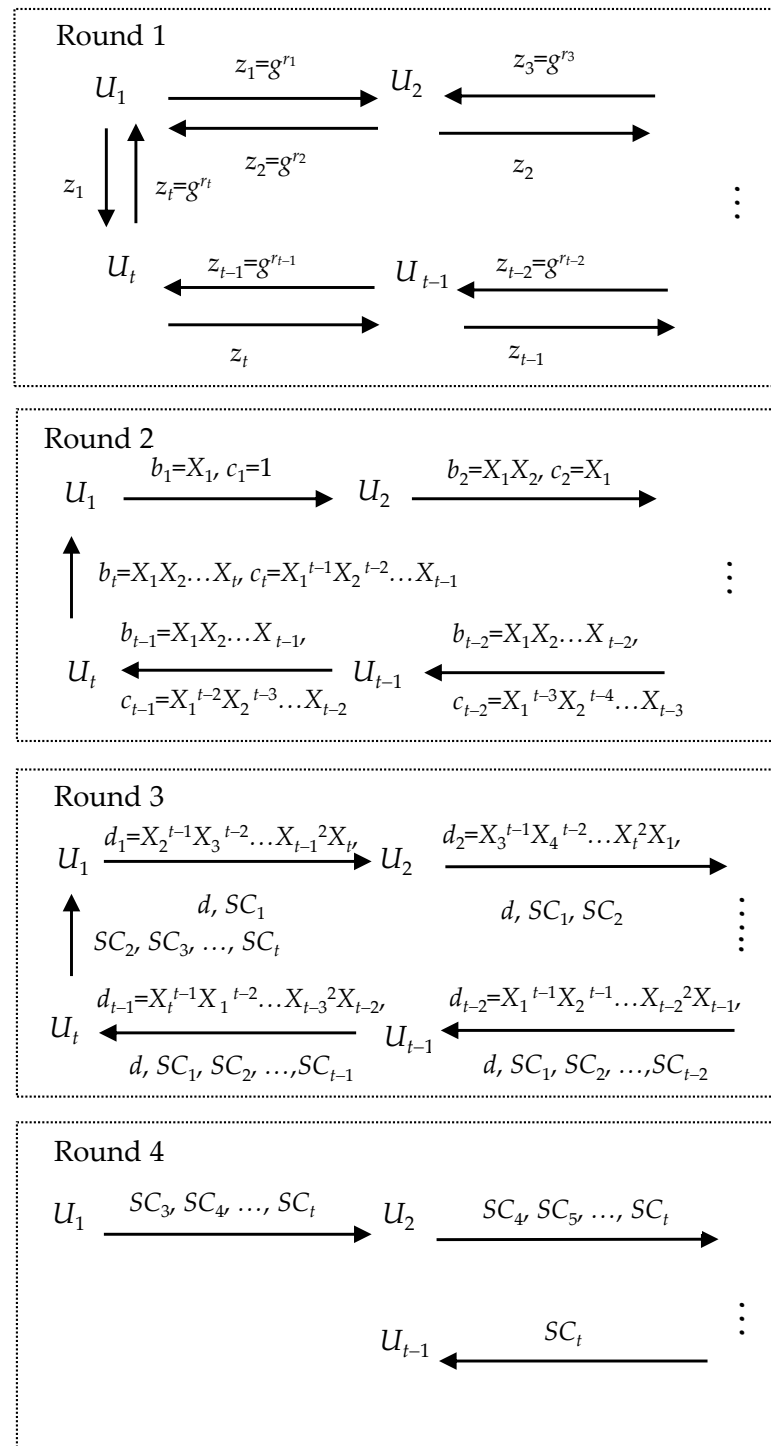

Figure 5. Improvement on cyclic protocol.

However, we argue that the above signature-based improvements on the Burmester-Desmedt protocol have at least two disadvantages, though they can resist member tampering attacks. First, the signature mechanism means that the group system needs to be equipped with Public Key Infrastructure (PKI) and issue digital certificates to ensure the authenticity of the members' public keys. In addition, the certificate chain may also increase the complexity of the group system. Second, the signature mechanism requires the

members of the group to generate, verify, transmit, and receive a considerable number of signatures. For example, each member in the improved broadcast version needs to generate and broadcast 1 signature and receive and verify the  $t - 1$  signature, if there are  $t$  members in the group. Moreover, the members of the group must run an extra round in an improved cyclic version. Obviously, these two disadvantages indicate a significant increase in the implementation overheads of the group system, when the Burmester-Desmedt protocol adopts the signature mechanism. Hence, the signature-based improvements on the Burmester-Desmedt protocol are not suitable for resource-constrained security environments, such as Bluetooth security [29,30]. The group systems based on Bluetooth low-energy devices are very popular in wireless personal area networks and Internet-of-Things (IoT). However, to maintain the low energy feature, Bluetooth security currently does not support the signature mechanism. Hence, an interesting open problem is whether one could enhance the Burmester-Desmedt protocol to prevent member tampering attacks without relying on resource-intensive public key algorithms, e.g., the signature and the public encryption. A related approach might be to rely on the cryptographic hash techniques to develop a more intricate hybrid structure for the Burmester-Desmedt protocol. This requires in-depth studies, including protocol design, efficiency evaluation, security analysis, etc. We leave it as future work.

## 5. Conclusions

One advantage of the Burmester-Desmedt protocol is scalability, that is, any  $t > 2$  members can establish a group session key after the protocol run. The scalability is very fit to ad hoc networks, where the number of members is often changing. However, we have shown that two malicious insiders in both group  $A$  and the group  $B$  can exploit its scalability to add the unknowing members of group  $A$  into the group  $B$  and make other members of the group  $B$  mistakenly believe that their group session key is shared with those unknowing members. Hence, owing to our member tampering attacks, the number of members is a security parameter and needs to be protected in the appropriate way when the scalable GKE protocol is deployed.

We proposed the signature-based improvement on the Burmester-Desmedt protocols, which is secure against our member tampering attacks. We compared our improvement with Katz-Yung protocol [15], because they are all based on the Burmester-Desmedt protocol and employ the signature schemes. In the broadcast version, the Katz-Yung protocol requires signing the messages of Round 1 and Round 2, respectively. Therefore, each member in the Katz-Yung protocol demands double signature operations compared with our improvement on the broadcast version. To the best of our knowledge, no other signature-based improvement on the cyclic version is proposed. However, under resource-constrained environments, our signature-based improvement is still not practical in view of the implementation costs.
