Abstract: The structural and gas-sensitive properties of *n*-N SnO₂/κ(ε)-Ga₂O₃:Sn heterostructures were investigated in detail for the first time. The κ(ε)-Ga₂O₃:Sn and SnO₂ films were grown by the halide vapor phase epitaxy and the high-frequency magnetron sputtering, respectively. The gas sensor response and speed of operation of the structures under H₂ exposure exceeded the corresponding values of single κ(ε)-Ga₂O₃:Sn and SnO₂ films within the temperature range of 25–175 °C. Meanwhile, the investigated heterostructures demonstrated a low response to CO, NH₃, and CH₄ gases and a high response to NO₂, even at low concentrations of 100 ppm. The current responses of the SnO₂/κ(ε)-Ga₂O₃:Sn structure to 10⁴ ppm of H₂ and 100 ppm of NO₂ were 30–47 arb. un. and 3.7 arb. un., correspondingly, at a temperature of 125 °C. The increase in the sensitivity of heterostructures at low temperatures is explained by a rise of the electron concentration and a change of a microrelief of the SnO₂ film surface when depositing on κ(ε)-Ga₂O₃:Sn. The SnO₂/κ(ε)-Ga₂O₃:Sn heterostructures, having high gas sensitivity over a wide operating temperature range, can find application in various fields.

Keywords: κ(ε)-Ga₂O₃:Sn; SnO₂; HVPE; magnetron sputtering; *n*-N heterostructure; gas sensors

1. Introduction

Sustainable development in terms of preserving the environment requires employment of a great number of sensors: biosensors, image sensors, motion sensors, and chemical sensors for indoor and outdoor as well as for industry-relevant gas surveillance and control. Wide bandgap metal oxide semiconductors tin dioxide (SnO₂) and gallium oxide (Ga₂O₃) are of high interest for the development of gas sensors and transparent contacts, finding applications in a number of devices [1–6]. Heterostructures based on metal oxide semiconductors allow the advantages of each component to be combined in a single structure [7]. Thus, superior gas-sensitive characteristics can be achieved for heterostructures compared to single semiconductors. It is reasonable to combine semiconductors with high catalytic activity and concentration of electrons, involved in the physico-chemical processes at chemisorption of gas molecules on the semiconductor surface.

SnO_2 is one of the most studied metal oxide semiconductors for gas sensor applications [1] primarily due to its high catalytic activity, which leads to a high gas sensitivity compared to other metal oxides. Chemisorption of gas molecules on the SnO_2 surface occurs with the involvement of free electrons. However, pure SnO_2 does not have a high electron concentration. Localization of electrons in this semiconductor can be achieved by forming heterostructures. Ga_2O_3 with an electron affinity $\chi = 4.0$ eV can be paired with SnO_2 , which is characterized by $\chi = 5.32$ eV [8], to form such a heterostructure. In turn, Ga_2O_3 needs to be doped to achieve the required concentration of free electrons. In this case, one can expect an increase in the sensitivity of such heterostructure to gases as compared to pure SnO_2 and Ga_2O_3 films.

Gallium oxide has several polymorphs [9–12] namely α , β , γ , δ , and $\kappa(\epsilon)$. Metastable $\kappa(\epsilon)\text{-Ga}_2\text{O}_3$ polymorph is of particular interest for the development of electronic devices due to its fundamental properties [13] such as the thermal stability up to 700 °C; the high bandgap E_g of 4.5–5.0 eV; availability of the ferroelectric properties; the high symmetry of a crystal lattice. $\kappa(\epsilon)\text{-Ga}_2\text{O}_3$ is a novel material in terms of sensors, since its gas sensitivity was researched for the first time in 2022 [14]. We have demonstrated that $\kappa(\epsilon)\text{-Ga}_2\text{O}_3\text{:Sn}$ films grown by the halide vapor phase epitaxy (HVPE) have a low resistance (i.e., high electron concentration), stable characteristics in the temperature range from 20 °C to 500 °C, and exhibit sensitivity to H_2 at room temperature (RT) [14]. In addition, the $\kappa(\epsilon)\text{-Ga}_2\text{O}_3$ polymorph meets the conditions of heteroepitaxy on a commercially available (0001) Al_2O_3 substrate better than monoclinic $\beta\text{-Ga}_2\text{O}_3$ [15]. Thus, doped $\kappa(\epsilon)\text{-Ga}_2\text{O}_3\text{:Sn}$ can be chosen to pair with SnO_2 to form a heterostructure.

$\text{SnO}_2/\beta\text{-Ga}_2\text{O}_3$ and $\text{SnO}_2/\kappa(\epsilon)\text{-Ga}_2\text{O}_3$ heterostructures have previously been investigated for the development of power diodes [16,17] and solar-blind avalanche photodetectors with high sensitivity [8]. $\beta\text{-Ga}_2\text{O}_3$ nanostructures covered with ultrathin layers of SnO_2 demonstrated high sensitivity to ethanol at $T = 400$ °C [18] and to H_2 in the range of $T = 25\text{--}200$ °C [19]. The gas-sensitive properties of $\text{SnO}_2/\kappa(\epsilon)\text{-Ga}_2\text{O}_3\text{:Sn}$ heterostructures have not been studied before.

The purpose of this work is to gain insight into the gas-sensitive properties of $\text{SnO}_2/\kappa(\epsilon)\text{-Ga}_2\text{O}_3\text{:Sn}$ heterostructures.

2. Materials and Methods

The following films were deposited on (0001) single crystal Al_2O_3 substrates: $\kappa(\epsilon)\text{-Ga}_2\text{O}_3\text{:Sn}$ and SnO_2 thin films as well as $\text{SnO}_2/\kappa(\epsilon)\text{-Ga}_2\text{O}_3\text{:Sn}$ heterostructure. The process of the $\kappa(\epsilon)\text{-Ga}_2\text{O}_3\text{:Sn}$ films growth was multistage. In the first stage, a 3- μm -thick semi-insulating (SI) GaN layer was deposited on the Al_2O_3 substrate by gas phase deposition employing a homemade reactor. This layer served as a template for the $\kappa(\epsilon)\text{-Ga}_2\text{O}_3\text{:Sn}$ film growth. In the second stage, a 1- μm -thick $\kappa(\epsilon)\text{-Ga}_2\text{O}_3$ layer in situ doped by Sn was deposited on the SI-GaN layer by HVPE using a hot-wall homemade reactor. Gaseous gallium chloride and oxygen were utilized as precursors. The doping of the $\kappa(\epsilon)\text{-Ga}_2\text{O}_3$ films was carried out during the growth by adding tin. The HVPE growth temperature of the $\kappa(\epsilon)\text{-Ga}_2\text{O}_3\text{:Sn}$ film was 600 °C. The analysis of current–voltage ($I\text{--}V$) and capacitance–voltage ($C\text{--}V$) characteristics applied at this stage showed that the effective donor concentration N_d of the films was $5.13 \times 10^{20} \text{ cm}^{-3}$.

120-nm-thick pure SnO_2 thin films were deposited by means of magnetron sputtering of an Sn (5N) target in an oxygen–argon plasma on Al_2O_3 and $\kappa(\epsilon)\text{-Ga}_2\text{O}_3\text{:Sn}$. An Edwards A-500 (Edwards, USA) setup was employed. To prepare $\text{SnO}_2/\kappa(\epsilon)\text{-Ga}_2\text{O}_3\text{:Sn}$ heterostructures, SnO_2 thin films were deposited through a mask with square-shaped slots of 1 mm \times 1 mm. The temperature of substrates during the deposition of the film was RT . The working pressure and power were kept at 7×10^{-3} mbar and 70 W, respectively. The oxygen concentration in the $\text{O}_2\text{+Ar}$ mixture was 56.1 ± 0.5 vol. %. The as-deposited SnO_2 films were annealed ex situ at $T = 600$ °C; for 4 hours in air. The estimates showed that the N_d value of these films was $5.26 \times 10^{17} \text{ cm}^{-3}$.

Pt contacts were deposited on the $\kappa(\epsilon)$ -Ga₂O₃:Sn and SnO₂ films (see Figure 1) by means of the magnetron sputtering. Pt contacts were chosen on the basis of their high stability at high temperatures and under exposure to various gases, which are of natural surroundings- and industrial relevance.

Figure 1. Schematic of the SnO₂/ $\kappa(\epsilon)$ -Ga₂O₃:Sn heterostructure.

X-ray diffraction (XRD) analysis of the samples was performed at DRON-6 diffractometer (Bourestnik, Petersburg, Russia) equipped with a copper anode (CuK_{α1}, $\lambda = 1.5406 \text{ \AA}$). The XRD patterns were registered in θ -2 θ scanning mode. The phase composition of the samples was identified by the position of the reflection peaks. XRD θ -2 θ curves were processed using the Scherrer method [20] to determine the characteristic size of the block in the direction perpendicular to the plane of epitaxial growth.

The chemical composition of the samples was studied by X-ray photoelectron spectroscopy (XPS). The XPS measurements were carried out using a hemispherical analyzer included in the ESCALAB 250Xi (Thermo Fisher Scientific, Waltham, MA, USA) laboratory spectrometer. The measurements were carried out using a monochromatized AlK_α radiation ($h\nu = 1486.6 \text{ eV}$). Survey and core (O1s, Sn3d, Ga3d) photoemission (PE) spectra were recorded at the analyzer transmission energy of 100 and 50 eV, respectively. The film's surface was irradiated with argon ions at an average energy of 3 eV for 60 s before XPS measurements to remove adsorbed atoms and molecules of contaminants. The analysis of the core spectra was processed employing the Avantage Data System software.

Measurement of transmission spectra was carried out using an Ocean Optics (Ocean Insight, Orlando, FL, USA) spectrometric system to determine the E_g of SnO₂ in the wavelength range of $\lambda = 300\text{--}600 \text{ nm}$. The transmission spectrum of $\kappa(\epsilon)$ -Ga₂O₃:Sn films was measured using a UV-VIS two-beam SPECORD (Analytik Jena, Jena, Germany) spectrophotometer in the range of $\lambda = 230\text{--}360 \text{ nm}$.

A high-resolution field emission scanning electron microscope (FESEM) Apreo 2S (Thermo Fisher Scientific, USA) operating at an accelerating voltage of 5 kV was employed to study the microrelief of the film surfaces with a high resolution.

Gas sensing measurements of the samples were performed in a dedicated sealed chamber with a volume of 100 cm³, equipped with a micro-probe Nextron MPS-CHH station (Nextron, Busan, Republic of Korea). A ceramic-type heater, installed in the sealed chamber, was used to heat the samples. The accuracy of temperature T control was $\pm 0.1 \text{ }^\circ\text{C}$. The experiments were carried out under dark conditions. Streams of pure dry air or gas mixture of pure dry air + H₂ were pumped through the chamber to measure the gas sensing characteristics of the samples. The H₂ concentration in the mixture was controlled by a gas mixing and delivery system Microgas F-06 (Intera, Moscow, Russia). A special generator (Khimelektonika SPE, Moscow, Russia) was used to produce pure dry air. The total flow rate of the gas mixtures through the chamber was 1000 sccm. The relative error of the gas mixture flow rate did not exceed 1.5%. A Keithley 2636 A (Keithley, Solon, OH, USA) source meter was utilized to measure the time dependences of the current I and the I - V characteristics of the samples. An E4980A RLC-meter (Agilent, Santa Clara, CA, USA) was applied to measure the C - V dependences. Additionally, gas sensing measurements of the samples were carried out under exposure to NH₃, CH₄, CO, NO₂, and O₂. A mixture of N₂ + O₂ was used to study the sensitivity of samples to O₂. To study the effect of relative humidity (RH) on the response of the samples to H₂, the pure dry air in one of the channels was passed through a bubbler with distilled water. Then it entered the homogenizer, where it was mixed with the pure dry air and/or pure dry air + H₂ mixture streams from the other channels. Varying the ratio of flows through the channels, we set the desired level of RH in

the measuring chamber. An HIH 4000 Honeywell capacitive sensor with an absolute error of $\pm 3.5\%$ was used to measure the RH. Just prior to these measurements, all the samples were subjected to heat treatment at $T = 500\text{ }^\circ\text{C}$ for 90 s in pure dry air to stabilize the contact properties and regenerate the surface.

3. Results and Discussion

3.1. Structural Properties

Figure 2a illustrates the θ -2 θ XRD pattern of the $\text{SnO}_2/\text{Ga}_2\text{O}_3$ heterostructure deposited on an Al_2O_3 substrate via a GaN template. The peaks at $2\theta = 41.8^\circ$ and 90.9° are associated with the (0006) and (0 0 0 12) reflections of the Al_2O_3 substrate (ICDD # 00-042-1468). A series of peaks at $2\theta = 19.2^\circ, 39.0^\circ, 60.0^\circ, 83.6^\circ,$ and 112.7° correspond to the 002, 004, 006, 008, and 0 0 10 planes of the $\kappa(\epsilon)\text{-Ga}_2\text{O}_3$ phase. (The calculation was made on the basis of the Bragg equation for the case of $\text{CuK}_{\alpha 1}$ anode ($\lambda = 1.5406\text{ \AA}$). The peaks at $2\theta = 34.7^\circ, 73.0^\circ,$ and 126.1° are due to the (0002), (0004), and (0006) reflections of the GaN template (AMCSD # 99-101-0461). Peaks corresponding to SnO_2 could not be distinguished due to possible overlapping by neighboring reflections of other phases. Thus, the (101) reflection of SnO_2 (AMCSD no. 99-100-8661) is close to the (0002) one of GaN, and the (111) reflection of SnO_2 is close to the (004) one of $\kappa(\epsilon)\text{-Ga}_2\text{O}_3$. The auxiliary vertical red lines of equal intensity depicted in Figure 2a are the tabular values of the SnO_2 reflection positions. In addition, difficulties in SnO_2 peaks identification may be caused by the low film thickness and the developed microrelief of the surface. Finally, the possible low crystallinity of the SnO_2 phase may be the reason for the absence of sharp peaks on the XRD pattern. In this case, broad humps of a low intensity may be present.

$\kappa(\epsilon)\text{-Ga}_2\text{O}_3\text{:Sn}$ and SnO_2 films are characterized by direct optical transitions according to the analysis of transmission spectra (see Figure 2b), where α is the absorption coefficient. E_g values were graphically calculated and proved to be equal to $4.61 \pm 0.01\text{ eV}$ and $3.76 \pm 0.01\text{ eV}$ for the $\kappa(\epsilon)\text{-Ga}_2\text{O}_3\text{:Sn}$ and SnO_2 films, respectively.

According to XPS analysis, the composition of the SnO_2 film includes Sn and O elements only. However, carbon (C) as a common contaminant was also observed in the subsurface layer a few nanometers thick. C atoms completely disappear after argon-etching for 60 s. Ga, Sn, O, and C lines were observed in the survey PE spectra of $\kappa(\epsilon)\text{-Ga}_2\text{O}_3\text{:Sn}$ film. The Sn concentration in this film appeared to be about 3 at. %, which indicates a high level of doping. Thus, the chemical analysis has shown that there are no third-party impurities in the composition of $\kappa(\epsilon)\text{-Ga}_2\text{O}_3\text{:Sn}$ and SnO_2 films, which confirms the high purity of the deposited films.

The analysis of the chemical state of Sn based on the $\text{Sn}3d_{5/2}$ PE line revealed the energy position of the main maximum of Sn at 486.5 and 486.3 eV (Figure 2c). The obtained values are in good agreement with the literature data [21,22] and correspond to the higher oxidation state of Sn– SnO_2 oxide. A lower value of the SnO_2 energy position for the $\kappa(\epsilon)\text{-Ga}_2\text{O}_3\text{:Sn}$ film indicates the effect of Ga_2O_3 on the charge state of SnO_2 . Previously, we have observed a similar effect of the $\text{Sn}3d_{5/2}$ PE line shift to low binding energies of the SnO_2 film doped with rare-earth elements and platinum group metals [21,22]. Analysis of the Ga chemical state in the $\kappa(\epsilon)\text{-Ga}_2\text{O}_3\text{:Sn}$ film based on the Ga3d PE line showed that Ga corresponds to the higher Ga_2O_3 oxide [23] (Figure 2d).

FESEM images of the SnO_2 films surface deposited on Al_2O_3 substrates and $\kappa(\epsilon)\text{-Ga}_2\text{O}_3\text{:Sn}$ film are displayed in Figure 2e,f, respectively. The microrelief of the SnO_2 film on Al_2O_3 (Figure 2e) contains small spherical grains with a diameter of $\sim 35\text{ nm}$ and large agglomerates with a characteristic size of $\sim 300\text{ nm}$. Whereas the microrelief of the SnO_2 film deposited on a $\kappa(\epsilon)\text{-Ga}_2\text{O}_3\text{:Sn}$ one (see Figure 2f) is represented by small grains with a diameter of $\sim 35\text{ nm}$ only. The formation of large agglomerates for these structures was not observed.

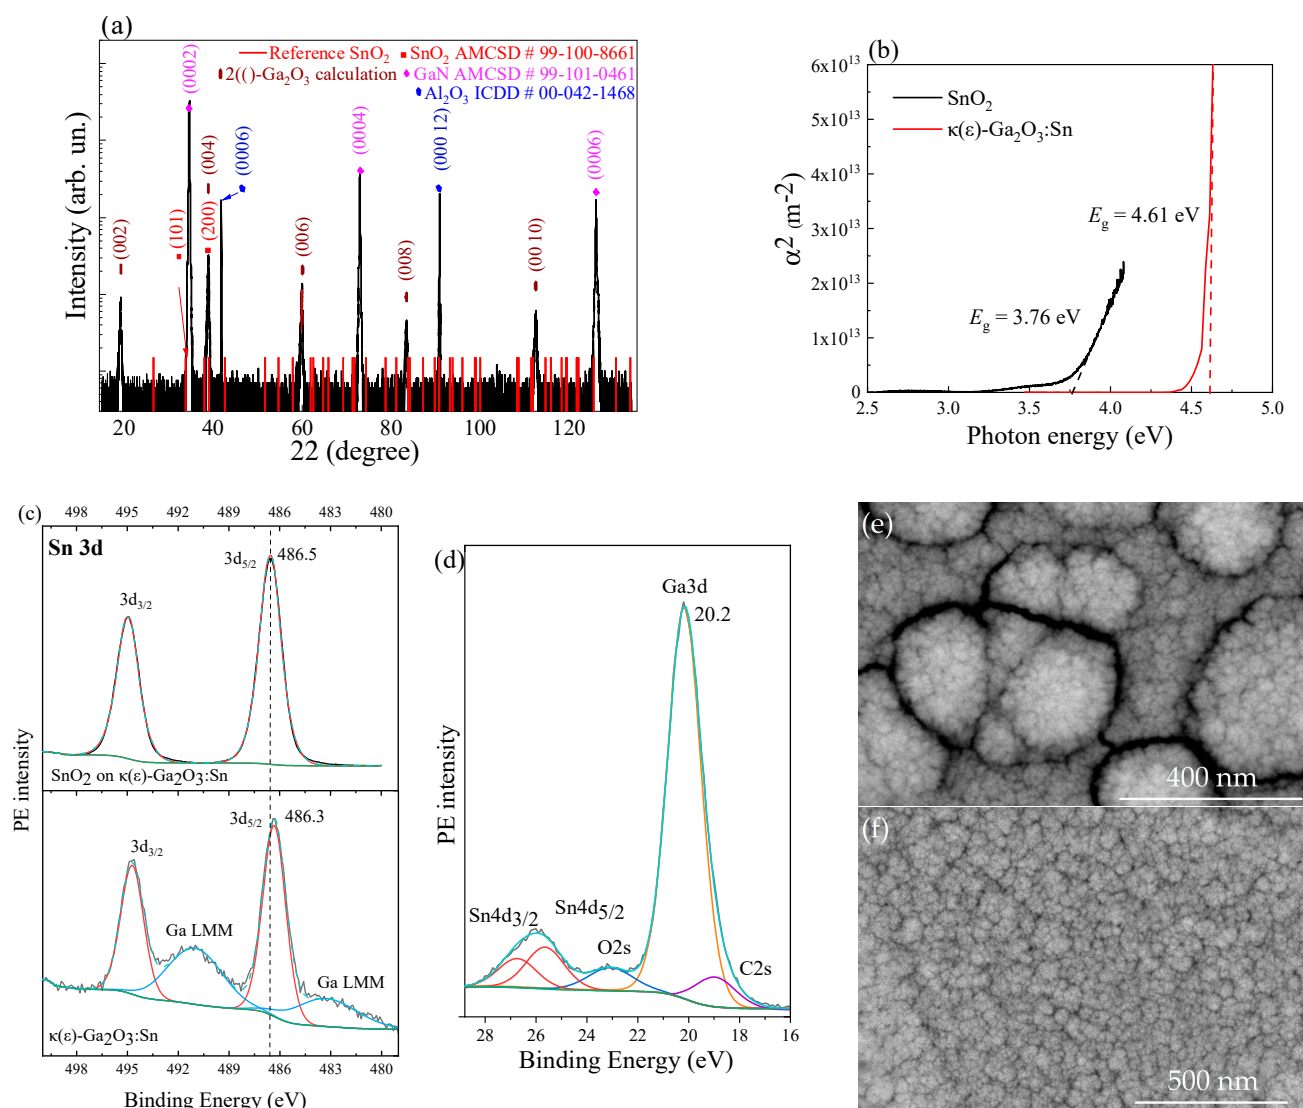

Figure 2. Structural characterization of the samples: (a) XRD pattern of the $\text{SnO}_2/\text{Ga}_2\text{O}_3$ heterostructure grown on $\text{GaN}/\text{Al}_2\text{O}_3$; (b) α^2 versus the photon energy for $\kappa(\epsilon)\text{-Ga}_2\text{O}_3:\text{Sn}$ and SnO_2 films; (c) $\text{Sn } 3d$ PE spectra of $\kappa(\epsilon)\text{-Ga}_2\text{O}_3:\text{Sn}$ and SnO_2 films; (d) $\text{Ga } 3d$, $\text{Sn } 4d$ PE lines for $\kappa(\epsilon)\text{-Ga}_2\text{O}_3:\text{Sn}$; FESEM images of the SnO_2 film deposited on Al_2O_3 (e) and $\kappa(\epsilon)\text{-Ga}_2\text{O}_3:\text{Sn}$ (f).

3.2. Gas-Sensitive Properties of the $\text{SnO}_2/\kappa(\epsilon)\text{-Ga}_2\text{O}_3:\text{Sn}$ heterostructure

The I - V characteristics of the SnO_2 thin films equipped with Pt contacts are linear in the range of applied voltages $U = -40$ – 40 V at RT as well as at higher T . Contrary to this, the I - V characteristics of the $\kappa(\epsilon)\text{-Ga}_2\text{O}_3:\text{Sn}$ films equipped with Pt contacts are nonlinear. The dependence of $\ln(I)$ on $U^{1/4}$ is linear, indicating the presence of a Schottky barrier at the Pt/ $\kappa(\epsilon)\text{-Ga}_2\text{O}_3:\text{Sn}$ interface [24]. The I value through the Pt/ $\kappa(\epsilon)\text{-Ga}_2\text{O}_3:\text{Sn}/\text{Pt}$ structures exceeds 0.1 A at $U > 12$ V which leads to the samples self-heating.

The $\text{SnO}_2/\kappa(\epsilon)\text{-Ga}_2\text{O}_3:\text{Sn}$ structure equipped with Pt contacts is a n - N isotype heterojunction and the Schottky barriers are connected in series. The I - V characteristics of such heterostructures are nonlinear and asymmetric as can be seen in Figure 3a. The $I(U = 4 \text{ V})/I(U = -4 \text{ V})$ ratio reaches the value of $\sim 2 \times 10^3$ at $T = 25^\circ\text{C}$, then drops by half as T increases to 150°C . The increase in reverse current with T rising is significantly higher than the increase in forward current. The forward-bias region of the I - V characteristics is approximated by the following function: $I_f = A_1 \times \exp(B_1 U)$, where I_f is a forward current; and A_1 and B_1 are the constants: $A_1 = (3.0 \pm 0.4) \times 10^{-6}$ A and $B_1 = 0.88 \pm 0.02 \text{ V}^{-1}$ at $T = 25^\circ\text{C}$. The reverse-bias region of the I - V characteristics can be approximated by a

similar function of $I_r = A_2 \times \exp(B_2 |U|)$, where I_r is a reverse current; A_2 and B_2 are the constants: $A_2 = (2.0 \pm 0.4) \times 10^{-9}$ A and $B_1 = 0.89 \pm 0.04$ V $^{-1}$ at $T = 25$ °C. The forward-bias mode of the structure corresponds to the application of a positive potential to the SnO $_2$ /Pt interface.

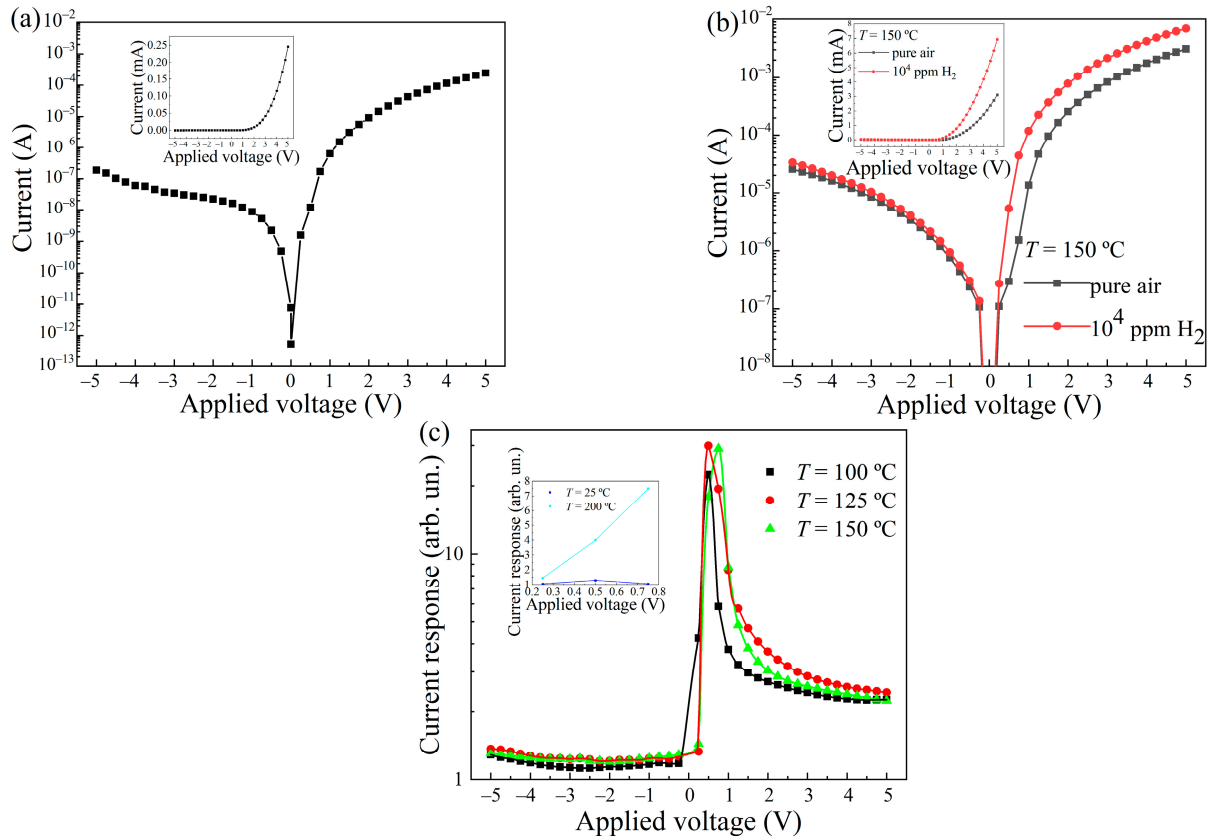

Figure 3. I – V characteristics of the SnO $_2/\kappa(\epsilon)$ -Ga $_2$ O $_3$:Sn heterostructure at $T = 25$ °C in pure dry air in semi-logarithmic coordinates (a), at $T = 150$ °C under exposure to 10^4 ppm of H $_2$ (b). The insertions show these I – V characteristics in linear coordinates. Dependence of the response to 10^4 ppm H $_2$ on the applied voltage at different temperatures (c), the insertion shows the response to 10^4 ppm H $_2$ on the applied voltage at $T = 25$ °C and 200 °C.

Exposure to H $_2$ leads to a reversible increase in the I through heterostructures at $T = 25$ – 200 °C. Figure 3b shows the change in the I – V characteristics of the SnO $_2/\kappa(\epsilon)$ -Ga $_2$ O $_3$:Sn heterostructure when exposed to 10^4 ppm of H $_2$ at $T = 150$ °C. The type of the functions, approximating the forward and reverse branches of the I – V characteristics, does not change with increasing T to 200 °C and under exposure to 10^4 ppm of H $_2$. The A_1 and A_2 increase, but B_1 and B_2 values decrease with T . The A_1 and A_2 values increase, whereas B_1 and B_2 practically do not change when exposed to H $_2$. Table 1 shows the A_1 , A_2 , B_1 , and B_2 values at $T = 150$ °C and under exposure to 10^4 ppm of H $_2$.

Table 1. A_1 , A_2 , B_1 , and B_2 at $T = 150$ °C and under exposure to 10^4 ppm H $_2$.

Conditions	A_1 (A)	A_2 (A)	B_1 (V $^{-1}$)	B_2 (V $^{-1}$)
Dry pure air	$(1.1 \pm 0.1) \times 10^{-4}$	$(1.1 \pm 0.1) \times 10^{-6}$	0.65 ± 0.03	0.65 ± 0.02
Dry pure air + 10^4 ppm H $_2$	$(2.6 \pm 0.3) \times 10^{-4}$	$(1.3 \pm 0.1) \times 10^{-6}$	0.66 ± 0.03	0.63 ± 0.03

To assess the effect of H₂ on the *I* through the SnO₂/κ(ε)-Ga₂O₃:Sn structures, the current response *S*₁ was calculated based on the experimental *I*–*V* characteristics by the following ratio:

$$S_1 = I_H / I_{air}, \tag{1}$$

where *I*_H is the current of the charge carrier through the SnO₂/κ(ε)-Ga₂O₃:Sn heterostructure in the gas mixture of pure dry air + H₂; *I*_{air} is the current of the charge carrier through the SnO₂/κ(ε)-Ga₂O₃:Sn heterostructure in pure dry air. The *S*₁ values calculated on the basis of the experimental *I*–*V* characteristics and time dependences of currents at a fixed *U* (see Figure 4a) coincide. The *S*₁ value depends on the magnitude and direction of the applied voltage (see Figure 3c). The highest response in the range of *T* = 100–125 °C was observed at *U* = 0.5 V, whereas the highest *S*₁ was observed at *U* = 0.75 V at *T* = 150 °C. At room temperature, the maximum *S*₁ was also noticed at *U* = 0.5 V (see Figure 3c, insertion). The response decreases exponentially with the applied voltage in the range of *U* = 1–5 V. *S*₁ values are significantly lower at the reverse-bias mode and decrease slightly with an increase in the reverse voltage |*U*_r| from 0.25 V to 2.5 V. Moreover, the response increases slightly with a further increase in |*U*_r| to 5 V.

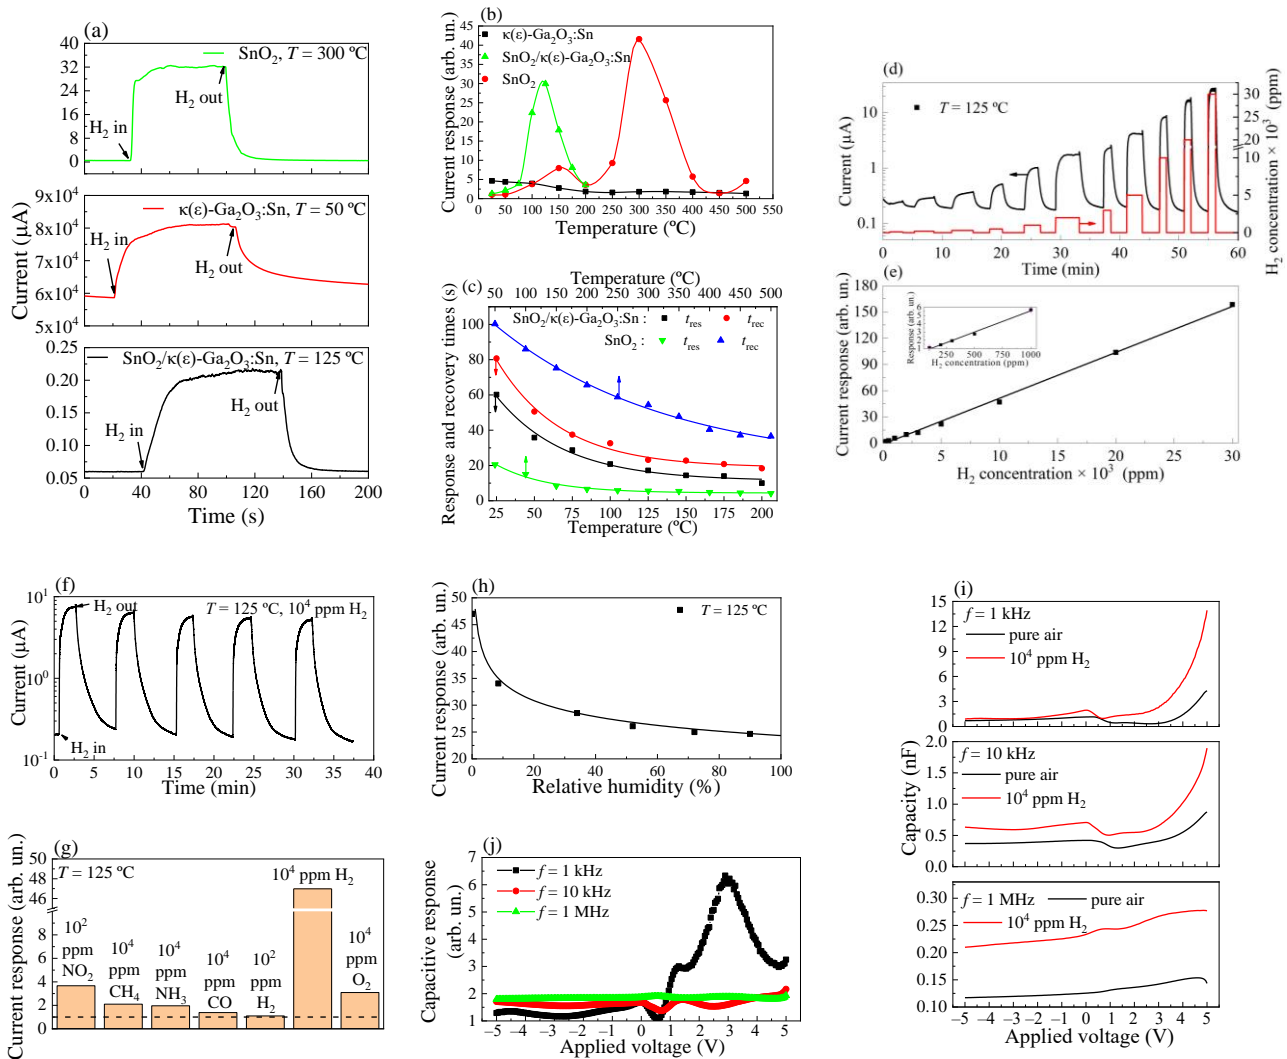

Figure 4. Gas-sensitive properties of *n*-N SnO₂/κ(ε)-Ga₂O₃:Sn heterostructure and other samples: (a) time dependences of current upon exposure to 10⁴ ppm of H₂; (b) temperature dependences of

responses to 10^4 ppm of H_2 ; (c) temperature dependences of response and recovery times upon exposure to 10^4 ppm of H_2 for different samples; (d) time dependence of current upon exposure to different H_2 concentration; (e) dependence of response on H_2 concentration; (f) time dependence of current upon cyclic exposure to 10^4 ppm of H_2 ; (g) responses to fixed concentrations of NO_2 , CH_4 , NH_3 , CO , H_2 , and O_2 ; (h) effect of the relative humidity on responses to 10^4 ppm of H_2 ; (i) dependences of the capacitive response on applied voltage upon exposure to 10^4 ppm of H_2 at $T = 125$ °C and different frequencies; (j) effect of 10^4 ppm of H_2 on C-V characteristics at $T = 125$ °C and different frequencies; dependences in (d–h) were measured at $T = 125$ °C and $U = 0.5$ V.

The temperature dependences of the sample's response to 10^4 ppm of H_2 are presented in Figure 4b. The $\kappa(\epsilon)$ - Ga_2O_3 :Sn films show the highest response to H_2 at $T = 25$ °C. The S_1 of $\kappa(\epsilon)$ - Ga_2O_3 :Sn films exceeds those of SnO_2 films in the temperature range of $T = 25$ – 50 °C; meanwhile, the S_1 of $\kappa(\epsilon)$ - Ga_2O_3 :Sn films decreases and S_1 of SnO_2 films increases drastically with further increase in T . Sensitivity of SnO_2 and $\kappa(\epsilon)$ - Ga_2O_3 :Sn films is based on reversible chemisorption of H_2 molecules on the semiconductor's surface according to the mechanisms described in refs. [14,25]. High sensitivity to H_2 at moderate temperatures ($T = 300$ °C) is characteristic of the SnO_2 thin films. Low S_1 for the $\kappa(\epsilon)$ - Ga_2O_3 :Sn films are caused by a significant influence of the bulk conductivity G_b , which does not depend on the charge state of the surface. The dependence of the $SnO_2/\kappa(\epsilon)$ - Ga_2O_3 :Sn heterostructures response to H_2 on temperature is characterized by a maximum at $T = 125$ °C. These samples demonstrate the highest S_1 in the range of $T = 75$ – 125 °C.

The experimental results displayed in Figure 4c prove that the $SnO_2/\kappa(\epsilon)$ - Ga_2O_3 :Sn heterostructures are characterized by the high speed of operation compared to the SnO_2 thin films when exposed to H_2 . The response t_{res} and recovery t_{rec} times were calculated to assess the speed of operation by the method described in ref. [9]. The calculated t_{res} and t_{rec} values can only be used to compare the speed of sensors operation at similar experimental conditions. t_{res} and t_{rec} decrease exponentially with T . t_{rec} and $t_{res} + t_{rec}$ of the $SnO_2/\kappa(\epsilon)$ - Ga_2O_3 :Sn structures are significantly lower than those of SnO_2 thin films at $T = 25$ – 200 °C. SnO_2 films are characterized by low t_{res} . The speed of operation for the $\kappa(\epsilon)$ - Ga_2O_3 :Sn films was not evaluated due to their low responses at $T > 50$ °C. These samples are of interest for developing room temperature H_2 sensors. The t_{res} and t_{rec} of these films under exposure to 10^4 ppm of H_2 at $T = 25$ °C are 349.2 s and 379.6 s, respectively. Obviously, $SnO_2/\kappa(\epsilon)$ - Ga_2O_3 :Sn heterostructures are the most interesting for highly sensitive H_2 sensors with high speed of operation and low operating temperatures. Therefore, our further attention will be focused on these structures.

The dependence of the $SnO_2/\kappa(\epsilon)$ - Ga_2O_3 :Sn structure response on the H_2 concentration n_{H_2} is linear (Figure 4d,e) in the n_{H_2} range of 100–30000 ppm. The I_{air} and I_H of the $SnO_2/\kappa(\epsilon)$ - Ga_2O_3 :Sn heterostructure decrease by 30% and 28%, respectively (see Figure 4f), during a cyclic exposure to H_2 (five cycles). At the same time, the current response decreased by only 17%. The observed decrease in response during cyclic exposure to H_2 is caused by the manifestation of chemisorbed hydrogen atoms with high binding energy. The temperature of 125 °C is not sufficient for the complete desorption of these hydrogen atoms from the semiconductor surface. Short-term heating of the structure at high temperatures can be used to regenerate the surface of semiconductors and for full desorption of H atoms [26]. The results of the long-term tests of the $SnO_2/\kappa(\epsilon)$ - Ga_2O_3 :Sn heterostructures at $T = 125$ °C and when exposed to 10^4 ppm of H_2 demonstrated opposite changes of S_1 . The samples after the experiments were stored in sealed packages. The long-term tests lasted 8 weeks with an interval between the experiments of 7–8 days. Just prior to each measurement the $SnO_2/\kappa(\epsilon)$ - Ga_2O_3 :Sn heterostructures were subjected to heat at $T = 500$ °C for 90 s. There were increases in response from ~30 arb. un. to 47 arb. un. during the long-term tests. Response increases mostly due to a decrease in I_{air} . The most significant changes in response were in the first 4 weeks of testing.

The responses of the $SnO_2/\kappa(\epsilon)$ - Ga_2O_3 :Sn heterostructure to NO_2 , CH_4 , NH_3 , CO , and O_2 gases at $T = 125$ °C was measured to evaluate its selectivity (Figure 4g). Noteworthy, is that I through heterostructure increases reversibly when exposed to 10^4 ppm of CH_4 ,

NH₃h and CO. The response to these gases has been calculated by equation (1). The I_H was replaced by I_g , where I_g is the charge carrier current through the SnO₂/κ(ε)-Ga₂O₃:Sn heterostructure in the gas mixture of pure dry air + reducing gas (CH₄, NH₃, or CO). The responses to CH₄, NH₃, and CO are insignificant compared to the S₁ to H₂, which equates to 29.92–46.98 arb. un. at $T = 125$ °C and $n_{H_2} = 10^4$ ppm.

It was found, that the I value of the SnO₂/κ(ε)-Ga₂O₃:Sn reversibly decreases when exposed to NO₂ and O₂. The responses to NO₂ (S_{NO_2}) and O₂ (S_{O_2}) have been calculated by the following equations, correspondently:

$$S_{NO_2} = I_{air}/I_{NO_2}, \quad (2)$$

$$S_{O_2} = I_N/I_{O_2}, \quad (3)$$

where I_{NO_2} is the charge carrier current through the SnO₂/κ(ε)-Ga₂O₃:Sn heterostructure in the gas mixture of pure dry air + NO₂; I_N is the charge carrier current through the SnO₂/κ(ε)-Ga₂O₃:Sn heterostructure in the nitrogen atmosphere; I_{O_2} is the charge carrier current through the SnO₂/κ(ε)-Ga₂O₃:Sn heterostructure in the gas mixture of N₂ + O₂. S₁ ratio when exposed to 100 ppm of H₂ at $T = 125$ °C happened to be 26.7 times lower than those for 100 ppm of NO₂ (Figure 4g). The SnO₂/κ(ε)-Ga₂O₃:Sn heterostructure also demonstrated relatively high response to O₂. The response to O₂ appears to be higher than to CH₄, NH₃, or CO at same concentration values. Hence, we have shown that SnO₂/κ(ε)-Ga₂O₃:Sn heterostructure is also attractive for developing highly sensitive NO₂ and O₂ sensors operating at low temperatures.

An increase in RH leads to a drop in the response of the SnO₂/κ(ε)-Ga₂O₃:Sn heterostructure to H₂ (Figure 4h). The most significant decrease in S₁ occurs when RH increases from 0 to 34 %. In the range of $RH = 34$ –90.0%, the response varies slightly.

Furthermore, the effect of 10⁴ ppm of H₂ on the C - V characteristics of the SnO₂/κ(ε)-Ga₂O₃:Sn heterostructures at $T = 125$ °C and signal frequencies $f = 1$ kHz, 10 kHz, and 1 MHz have been studied. The results are illustrated in Figure 4i,j. Evidently, exposure to H₂ leads to a reversible increase in the electrical capacity of the structures. The capacitive response S_C has been calculated by the following equation:

$$S_C = C_H/C_{air}, \quad (4)$$

where C_H is the electrical capacitance of SnO₂/κ(ε)-Ga₂O₃:Sn heterostructure in the gas mixture of pure dry air + H₂; and C_{air} is the electrical capacitance of structures in pure dry air. Visibly, the S_C (see Figure 4i) is significantly lower than the S₁ (Figure 3c). At $f = 10$ kHz and 1 MHz the capacitive response varies weakly. The highest S_C value is observed in the range of $U = 0.95$ –5.00 V at $f = 1$ kHz and has a maximum at $U = 2.9$ V.

3.3. The Mechanism of the Sensory Effect

Initially, the resistance of the Pt/κ(ε)-Ga₂O₃:Sn interface is low and the Pt/SnO₂ contact is ohmic. The change in the potential barrier at Pt/κ(ε)-Ga₂O₃:Sn and Pt/SnO₂ interfaces upon exposure to gases can be neglected. The observed high responses of the SnO₂/κ(ε)-Ga₂O₃:Sn heterostructure at $T = 25$ –175 °C; are due to the formation of the n - N isotypic heterojunction, where SnO₂ is the base.

Diffusion of H atoms up to the SnO₂/κ(ε)-Ga₂O₃:Sn interface at $T = 25$ –175 °C; is unlikely. Changes of I and C upon exposure to H₂ occur mainly due to the chemisorption of gas molecules on semiconductor's surface. In the air atmosphere within a temperature range of $T = 25$ –175 °C, the oxygen chemisorbs mainly in a molecular form on metal oxide semiconductors surface and captures electrons from their conduction band [25,27]. The reaction of reversible chemisorption of oxygen molecules can be represented as follows:

where S_a is a free adsorption center; e is the electron charge; $O_2^-(c)$ is the chemisorbed oxygen ion. As a result of reaction (4), an electron-depleted region is formed in the near-surface part of the semiconductor. A negative charge on the surface causes the upward of energy bands bending at eV_s , where V_s is the surface potential and $eV_s \sim N_i^2$, where N_i is the surface density of chemisorbed oxygen ions. In our case, the Debye length L_D for SnO_2 exceeds the grain size and the effect of grain boundaries on the transport of charge carriers in a semiconductor can be ignored. Oxygen chemisorption weakly changes the electrical conductivity of the $\kappa(\epsilon)$ - $Ga_2O_3:Sn$ films due to the low contribution of the surface conductivity G_s to the total conductivity of G_t . Thus, changes in the current during the chemisorption of gases are mainly due to changes in the concentration of charge carriers in the SnO_2 .

$G_t = G_b + G_s$ and the relationship between G_t and eV_s in our case is described by the following equation [28]:

$$G_t = G_b \times [1 - (L_D/D) \times [eV_s/(kT)]], \quad (6)$$

where D is the SnO_2 film thickness; k is the Boltzmann constant. An increase in the eV_s due to the oxygen molecule's chemisorption on the SnO_2 surface leads to a drop of G_t . The increase in G_t when exposed to H_2 is caused by the interaction of H_2 molecules with previously chemisorbed $O_2^-(c)$ on the SnO_2 surface. This interaction can be represented as follows:

As a result of reaction (7), a neutral H_2O molecule is formed and desorbed, an electron returns to the conduction band of SnO_2 , the eV_s decreases and the finally G_t increases. When exposed to NO_2 the following reactions take place [29]:

NO_2 molecules chemisorb onto free adsorption centers and capture electrons from the SnO_2 conduction band. Meanwhile, eV_s is proportional to $(N_i + N_{NO_2})^2$ in the mixtures of air + NO_2 , where N_{NO_2} is the surface density of chemisorbed NO_2^- ions [25,27]. An additional negative charge on the surface of the SnO_2 film leads to a greater decrease in G_t . Further, NO_2^- ions are dissociated to form chemisorbed $O^-(c)$ ions and gaseous NO molecules. In the low temperature region, atomic $O^-(c)$ ions associated to $O_2^-(c)$ form and a free electron e^- , which returns to the conduction band of the semiconductor.

The $\kappa(\epsilon)$ - $Ga_2O_3:Sn$ film is a source of electrons that are involved in reactions (5) and (8) with the gas molecules on the SnO_2 surface. This causes a high response of heterostructure at $T = 75\text{--}175$ °C. The base region (SnO_2) is filled with electrons from the $\kappa(\epsilon)$ - $Ga_2O_3:Sn$ film with T rising, G_b of SnO_2 increases and the response decreases. SnO_2 films deposited on $\kappa(\epsilon)$ - $Ga_2O_3:Sn$ are characterized by the absence of large agglomerates (see Figure 2e,f). This leads to an increase in the specific surface area of SnO_2 and the surface density of adsorption centers for gas molecules.

Table 2 shows a comparison of the responses and optimal operating temperatures of structures based on the Ga_2O_3 polymorphs when exposed to H_2 and NO_2 [9,14,18,19,30–42]. n_g is a gas concentration. $SnO_2/\kappa(\epsilon)$ - $Ga_2O_3:Sn$ heterostructure in comparison with other items listed in this table is characterized by relatively high sensitivity to H_2 and NO_2 at a relatively low operating temperature. Ga_2O_3 -based structures with higher responses to gases are characterized by high operating temperatures [9,30,34–37,41,42], low speed of operation [18,19], or are diode-type sensors based on high-cost materials [31,32,39]. $SnO_2/\kappa(\epsilon)$ - $Ga_2O_3:Sn$ heterostructures demonstrate relatively high responses to H_2 and NO_2 at lower temperatures in comparison with the heterostructures based on other metal

oxides (see Table 3). Nano-structured heterostructures are characterized by higher responses to NO₂ but generally do not differ in high speed of operation.

4. Conclusions

The structural and gas-sensitive properties of the n -N SnO₂/ $\kappa(\epsilon)$ -Ga₂O₃:Sn heterostructures were investigated for the first time. The $\kappa(\epsilon)$ -Ga₂O₃:Sn and SnO₂ films were obtained by the halide vapor phase epitaxy and the high-frequency magnetron sputtering, respectively. The $\kappa(\epsilon)$ -Ga₂O₃:Sn crystalline film has a bandgap of 4.61 ± 0.01 eV. The SnO₂

nanocrystalline film has a bandgap of 3.76 ± 0.01 eV and is characterized by a developed microrelief of the surface, represented by grains with a size of ~ 35 nm. Exposure to H_2 leads to an increase in electrical current and capacitance of $SnO_2/\kappa(\epsilon)-Ga_2O_3:Sn$ structures. The current response of heterostructures to H_2 significantly exceeds the capacitive one. Gas sensor response and speed of operation of the $SnO_2/\kappa(\epsilon)-Ga_2O_3:Sn$ heterostructure under H_2 exposure overperform those of the single $\kappa(\epsilon)-Ga_2O_3:Sn$ and SnO_2 films in the temperature range of 25–175 °C. This heterostructure demonstrates a low response to CO , NH_3 , and CH_4 and a high response to NO_2 even at low concentrations. The current responses of $SnO_2/\kappa(\epsilon)-Ga_2O_3:Sn$ heterostructure to 10^4 ppm of H_2 and 100 ppm of NO_2 at 125 °C were 30–47 A.U. and 3.7 A.U., correspondingly. The sensory effect is realized mainly due to the chemisorption of gas molecules on the SnO_2 surface, which is the base region of the heterostructure. The $\kappa(\epsilon)-Ga_2O_3:Sn$ film is a source of electrons that are involved in reactions with gas molecules on the SnO_2 film surface. The SnO_2 film deposited on the $\kappa(\epsilon)-Ga_2O_3:Sn$ film is characterized by a more developed surface microstructure. This leads to an increase in the surface density of adsorption centers for gas molecules. The advantages of the $SnO_2/\kappa(\epsilon)-Ga_2O_3:Sn$ heterostructure for gas sensors are shown, the main one being high sensitivity at relatively low operating temperatures. Doubtfully, this structure has every chance of being the base of the sensor.
