

Supplementary Files

Supplemental Figure S1

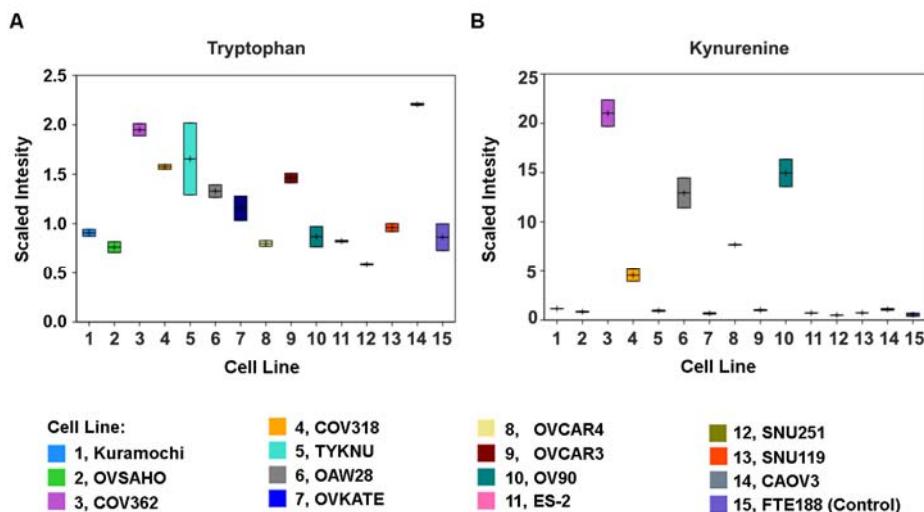

Figure S1. Higher tryptophan and kynurenine levels in the subset of HGSOC cells. Changes in the cellular content of tryptophane (A) and its metabolites Kynurenine (B) and 5-hydroxytrptamine/serotonin (Figure 4 in the text) were determined. Relative contents of the respective metabolites are expressed as scaled intensity in the Y-axis against the cell types presented in the X-axis. Center line in boxes in the box plot denotes the median value. The upper and lower borders define the two measurements of scaled intensity.

Supplemental Methods

Metabolic Analysis at Metabolon, Inc.

Sample Accession: Frozen pellets of the replicate samples of the cell lines were inventoried and immediately stored at -80°C. Each sample received was accessioned into the Metabolon LIMS system and was assigned by the LIMS a unique identifier that was associated with the original source identifier only. This identifier was used to track all sample handling, tasks, results, etc. The samples (and all derived aliquots) were tracked by the LIMS system. All portions of any sample were automatically assigned their own unique identifiers by the LIMS when a new task was created; the relationship of these samples was also tracked. All samples were maintained at -80°C until processed.

Sample Preparation: Samples were prepared using the automated MicroLab STAR® system (Hamilton Company, Reno, NV, USA). Recovery standards were added prior to the extraction process for quality control (QC) purposes. Proteins in the cell lysates were precipitated with methanol followed by centrifugation. The methanol extract was divided into five fractions: two for analysis by two separate reverse phase (RP)/UPLC-MS/MS methods with positive ion mode electrospray ionization (ESI), one for analysis by RP/UPLC-MS/MS with negative ion mode ESI, one for analysis by HILIC/UPLC-MS/MS with negative ion mode ESI, and one sample was reserved for backup. Organic solvent was evaporated and the extracted samples were stored under nitrogen prior to analysis.

Quality control (QC): Aliquots of pooled samples or a pool of well-characterized human plasma was used as technical replicate. A defined set of QC standards were spiked into every analyzed sample to monitor instrument performance and chromatographic alignment. Instrument variability was determined by calculating the median relative standard deviation (RSD) for the standards that were added to each sample prior to injection into the mass spectrometers. Tables S1 and S2 describe these QC samples and standards. Overall process variability was determined by calculating the median RSD for all endogenous metabolites present in 100% of the pooled matrix samples.

Table S1. Quality Control Samples

Type	Description	Purpose
MTRX	Large pool of human plasma maintained by Metabolon that has been characterized extensively.	Assure that all aspects of the Metabolon process are operating within specifications.
CMTRX	Pool created by taking a small aliquot from every customer sample.	Assess the effect of a non-plasma matrix on the Metabolon process and distinguish biological variability from process variability.
PRCS	Aliquot of ultra-pure water	Process Blank used to assess the contribution to compound signals from the process.
SOLV	Aliquot of solvents used in extraction.	Solvent Blank used to segregate contamination sources in the extraction.

Table S2. Quality Control Standards

Type	Description	Purpose
RS	Recovery Standard	Assess variability and verify performance of extraction and instrumentation.
IS	Internal Standard	Assess variability and performance of instrument.

Data Quality: Instrument and Process Variability: Instrument variability was determined by calculating the median relative standard deviation (RSD) for the internal standards that were added to each sample prior to injection into the mass spectrometers. Overall process variability was determined by calculating

the median RSD for all endogenous metabolites (i.e., non-instrument standards) present in 100% of the Client Matrix samples, which are technical replicates of pooled client samples. Values for instrument and process variability meet Metabolon's acceptance criteria as shown in the table S3.

Table S3. Data Quality

QC Sample	Measurement	Median RSD
Internal Standards	Instrument Variability	5%
Endogenous Biochemicals	Total Process Variability	7%

Ultrahigh Performance Liquid Chromatography-Tandem Mass Spectroscopy (UPLC-MS/MS): Waters ACQUITY ultra-performance liquid chromatography (UPLC) and a Thermo Scientific Q-Exactive high resolution/accurate mass spectrometer interfaced with a heated electrospray ionization (HESI-II) source and Orbitrap mass analyzer operated at 35,000 mass resolution were used. Sample extracts were dried, then reconstituted in solvents compatible to each of the four methods as follows. Each reconstitution solvent contained a series of standards at fixed concentrations to ensure injection and chromatographic consistency. One aliquot was analyzed using acidic positive ion conditions, chromatographically optimized for more hydrophilic compounds. In this method, the extract was gradient eluted from a C18 column (Waters UPLC BEH C18-2.1x100 mm, 1.7 µm) using water and methanol, containing 0.05% perfluoropentanoic acid (PFPA) and 0.1% formic acid (FA). Another aliquot was also analyzed using acidic positive ion conditions; however, it was chromatographically optimized for more hydrophobic compounds. In this method, the extract was gradient eluted from the same afore mentioned C18 column using methanol, acetonitrile, water, 0.05% PFPA and 0.01% FA and was operated at an overall higher organic content. Another aliquot was analyzed using basic negative ion optimized conditions using a separate dedicated C18 column. The basic extracts were gradient eluted from the column using methanol and water, however with 6.5mM Ammonium Bicarbonate at pH 8. The fourth aliquot was analyzed via negative ionization following elution from a HILIC column (Waters UPLC BEH Amide 2.1x150 mm, 1.7 µm) using a gradient consisting of water and acetonitrile with 10mM Ammonium Formate, pH 10.8. The MS analysis alternated between MS and data-dependent MSⁿ scans using dynamic exclusion. The scan range varied between methods but covered 70-1000 m/z. Raw data files were archived and extracted for further analysis.

Bioinformatics: The informatics system consisted of four major components, the Laboratory Information Management System (LIMS), the data extraction and peak-identification software, data processing tools for QC and compound identification, and a collection of information interpretation and visualization tools for use by data analysts. The hardware and software foundations for these informatics components were the LAN backbone, and a database server running Oracle 10.2.0.1 Enterprise Edition.

LIMS: The purpose of the Metabolon LIMS system was to enable fully auditable laboratory automation through a secure, easy to use, and highly specialized system. The scope of the Metabolon LIMS system encompasses sample accessioning, sample preparation and instrumental analysis and reporting and advanced data analysis. All of the subsequent software systems are grounded in the LIMS data structures. It has been modified to leverage and interface with the in-house information extraction and data visualization systems, as well as third party instrumentation and data analysis software.

Data Extraction and Compound Identification: Raw data was extracted, peak-identified and QC processed using Metabolon's hardware and software. Compounds were identified by comparison to library entries of purified standards or recurrent unknown entities. Metabolon maintains a library based on authenticated standards that contains the retention time/index (RI), mass to charge ratio (*m/z*), and

chromatographic data (including MS/MS spectral data) on all molecules present in the library. Furthermore, biochemical identifications are based on three criteria: retention index within a narrow RI window of the proposed identification, accurate mass match to the library +/- 10 ppm, and the MS/MS forward and reverse scores between the experimental data and authentic standards. The MS/MS scores are based on a comparison of the ions present in the experimental spectrum to the ions present in the library spectrum. While there may be similarities between these molecules based on one of these factors, the use of all three data points can be utilized to distinguish and differentiate biochemicals. More than 3300 commercially available purified standard compounds have been acquired and registered into LIMS for analysis on all platforms for determination of their analytical characteristics. Additional mass spectral entries have been created for structurally unnamed biochemicals, which have been identified by virtue of their recurrent nature (both chromatographic and mass spectral). These compounds have the potential to be identified by future acquisition of a matching purified standard or by classical structural analysis.

Curation: A variety of curation procedures were carried out to ensure that a high-quality data set was made available for statistical analysis and data interpretation. The QC and curation processes were designed to ensure accurate and consistent identification of true chemical entities, and to remove those representing system artifacts, mis-assignments, and background noise. Metabolon data analysts use proprietary visualization and interpretation software to confirm the consistency of peak identification among the various samples. Library matches for each compound were checked for each sample and corrected if necessary.

Metabolite Quantification and Data Normalization: Peaks were quantified using area-under-the-curve. For studies spanning multiple days, a data normalization step was performed to correct variation resulting from instrument inter-day tuning differences. Essentially, each compound was corrected in run-day blocks by registering the medians to equal one (1.00) and normalizing each data point proportionately (termed the "block correction"). For studies that did not require more than one day of analysis, no normalization is necessary, other than for purposes of data visualization. Biochemical data were normalized to total protein as determined by Bradford assay to account for differences in metabolite levels due to differences in the amount of material present in each sample.

Statistical Calculations: For many studies, two types of statistical analysis are usually performed: (1) significance tests and (2) classification analysis. Standard statistical analyses were performed in ArrayStudio 7.2 (Qiagen OmicSoft, Cary, NC) on log transformed data to compare the data from the experimental groups using Multivariate ANOVA. For those analyses not standard in ArrayStudio, the programs R (<http://cran.r-project.org/>) or JMP JMP software (JMP Inc. Cary, NC) were used. Post-hoc P-values and false discovery rates were calculated by determining the p- and q-values using Storey's method (Storey, J.D.; Tibshirani, R. Statistical significance for genomewide studies. *Proc Natl Acad Sci U S A* 2003, 100, 9440-9445, doi:10.1073/pnas.1530509100). Only the data with the p-value of < 0.05 were considered significant. FDR values of < 0.05 were considered significant. Complete dataset with p- and q-values are deposited at the NIH Common Fund's National Metabolomics Data Repository:

(<https://www.metabolomicsworkbench.org/data/DRCCMetadata.php?Mode=Project&ProjectID=PR001259>).

Hierarchical Clustering: Unsupervised Hierarchical clustering method was used for clustering the data. and can show large-scale differences. Clustering used the Euclidean distance, where each sample is a vector with all of the metabolite values.

Principal Components Analysis (PCA). Unsupervised PCA was carried out to reduces the dimension of the data. Each principal component is a linear combination of every metabolite and the principal components are uncorrelated. The number of principal components is equal to the number of observations. In 2D-PCA, the first principal component is computed by determining the coefficients of the metabolites

that maximizes the variance of the linear combination. The second component finds the coefficients that maximize the variance with the condition that the second component is orthogonal to the first. In 3D-PCA, along with the above-mentioned components, the third component, which is orthogonal to the first two components is included. The total variance is defined as the sum of the variances of the predicted values of each component, and for each component, the proportion of the total variance is computed. The total variance is defined as the sum of the variances of the predicted values of each component), and for each component, the proportion of the total variance is computed.

Experimental Summary

Replicate cell pellet samples representing fourteen ovarian cancer lines and control cell line were collected and analyzed for global metabolic profiling. Global metabolic profiles were determined using Metabolon metabolomic analysis platform. Following normalization to Bradford protein concentration, log transformation and imputation of missing values, if any, with the minimum observed value for each compound, Welch's two-sample *t*-test was used to identify biochemicals that differed significantly between experimental groups. A summary of the numbers of biochemicals that achieved statistical significance ($p \leq 0.05$) is presented in Table 4. An estimate of the false discovery rate (*q*-value) is calculated to take into account the multiple comparisons that normally occur in metabolomic-based studies. For example, when analyzing 200 compounds, one would expect to see about 10 compounds meeting the $p \leq 0.05$ cut-off by random chance. The *q*-value describes the false discovery rate; a low *q*-value ($q < 0.05$) is an indication of high confidence in a result. The present dataset comprises a total of 731 compounds of known identity (Table 5). Complete set of data along with the p- and q-values are deposited at the NIH Common Fund's National Metabolomics Data Repository:

(<https://www.metabolomicsworkbench.org/data/DRCCMetadata.php?Mode=Project&ProjectID=PR001259>)

Data Presentation

Relative contents of the respective metabolites are expressed as scaled intensity in the Y-axis against the cell types presented in the X-axis. Scaled intensity is an arbitrary unit relative to the overall median 1 for the test metabolite. Raw intensity data of each metabolite was scaled on the intensity of the commercially available biochemical metabolite analyzed using the same instrument. Data points are presented as boxes in the box plot in which the center line in boxes in denotes the median value. The upper and lower borders define the 25th and 75th quartiles of scaled intensity.

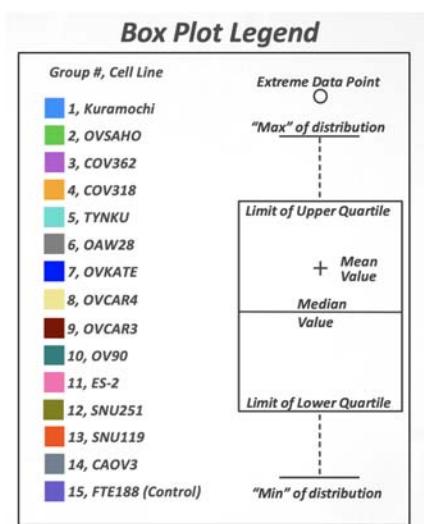

Table S4: Summary of the number of metabolites identified. Statistical analyses were performed in ArrayStudio version 7.2 (Qiagen OmicSoft, Cary, NC) on log transformed data to compare the data from the experimental groups using Multivariate ANOVA. Post-hoc P-values and false discovery rates were calculated by determining the p- and q-values using Storey's method.
