**Abstract:** Carbon nano peapods, with their electronic properties and spintronics, have attracted great attention regarding their potential applications when combined with fullerenes or their derivatives encapsulated inside. Herein, we have designed and synthesized a series of fullerene derivatives with different functional groups, which are then encapsulated into single-walled carbon nanotubes (SWCNTs). Accurate morphological characterization with high-resolution TEM reveals a clear correlation between the filling ratio of the peapods and the steric bulk of the functionalized groups. Further spectroscopic characterizations reveal diameter-selective interactions between the fullerene derivatives and SWCNTs, which, in turn, influence the electronic structures of the nanotubes. Our results have shed new light on the controlled synthesis and property-tuning of nano peapods.

**Keywords:** peapod; carbon nanotubes; fullerenes; fullerene derivatives

## 1. Introduction

Since the discovery of a new type of hybrid carbon nanostructure, with fullerenes inside carbon nanotubes (CNTs), the so-called peapods [1], a range of hollow fullerenes [2–4] and metallofullerenes [5–8], have been encapsulated into SWCNTs. Accordingly, carbon nanotubes acting as nano-containers [9] and nano-reactors [10] have become a hot topic in terms of the exploitation and modification of their excellent electronic [11] and mechanical properties [12] in nanomaterial science. It is well established that the fullerene dopants can modify the electronic structures of SWCNTs [13–15] and lead to advantageous physical and chemical properties that could be utilized in many applications, such as nanoelectronics [16,17], quantum computing [15,18], and thermoelectricity [19,20].

It has gradually become understood that the unprecedented properties and functions of peapods are due largely to the interactions between fullerenes and SWCNTs induced by the attractive physical and chemical properties of the encapsulated fullerenes. More importantly, the exteriors of fullerene molecules can be involved in organic reactions, facilitating the attachment of functional groups to their carbon cages and thereby imparting numerous distinct properties. As a consequence, the fullerene cages serve as vehicles for transferring some electrostatically bonded complexes into carbon nanotubes, which exert a shielding effect on the optical properties of the guest molecules, such as emission quenching [21,22]. This means that the combination of functionalized fullerenes with unique properties and SWCNTs holds paramount significance. However, the previous studies into the encapsulation of functionalized fullerenes into SWCNTs have focused mainly on the control of specific orientations and the packing of molecules inside SWCNTs, as observed via high-resolution TEM [23–25]. The interactions between different fullerene

derivatives and SWCNTs in their peapod structures, which are closely related to the resultant properties of the peapods, are yet to be systematically studied.

In this work, pristine  $C_{60}$  and three  $C_{60}$ -derivatives (**1**, **2** and **3**) containing different functional groups [23] have been successfully inserted into SWCNTs. The structural diagrams of are depicted in Figure 1. Our results reveal that the filling ratio of the resultant peapods decreases with the increasing steric bulk of the addends. More importantly, we confirm, for the first time, that the encapsulation of these fullerene derivatives is highly dependent on the diameter of the SWCNTs, as evidenced via the Raman and UV spectroscopic results.

**Figure 1.** Structural diagrams of  $C_{60}$  (a) and its derivatives **1** (b), **2** (c) and **3** (d).

## 2. Results and Discussion

The resultant peapod structures with  $C_{60}$ , **1**, **2** and **3** inside SWCNTs are first investigated via HR-TEM (Figure 2). Meanwhile, based on the synthesis procedures of peapods, no other substance other than  $C_{60}$ , **1**, **2** and **3** could contribute a round shape in the HR-TEM images, suggesting the successful encapsulation of the fullerene dopants inside SWCNTs. Moreover, we have roughly estimated the filling rate of peapods as being above 80% via HR-TEM observation (Figure S13 in Supplementary Materials). It appears that the filling ratio of the peapods decreases along with the increasing bulk of the addends in these hybrids, possibly due to the increasing steric hindrance of the functional groups. Moreover, the derivatives (**1**, **2** and **3**) exhibit largely disordered arrangements, with larger inter-fullerene spacing inside SWCNTs (Figure 2b–d) than that of  $C_{60}$ @SWCNT peapods (Figure 2a). In particular, the short and rigid organic group attaching to the fullerene cage is clearly seen in the **1**@SWCNT peapods (Figure 2b). Furthermore, it has been observed that the substantial size of the side group in compound **3** impedes its encapsulation within the SWCNT, and leads, instead, to a conspicuous attachment onto the external surface of the nanotubes, adopting folded conformations (Figure 2d). In contrast, the attachment of the fullerene moiety on the surface of the SWCNT is not obvious in  $C_{60}$ @SWCNT, **1**@SWCNT, and **2**@SWCNT, but these fullerene derivatives are largely encapsulated. These results confirm a size effect of the side group of fullerene derivatives on the encapsulation ratio and even the attachment on the SWCNT surface. Moreover, a collapse in the fullerene entities is observed in **1**@SWCNT, **2**@SWCNT, and **3**@SWCNT (Figure 2b–d), but the spherical structure of  $C_{60}$  is rather intact, as found in  $C_{60}$ @SWCNT. These results indicate that the functionalized derivatives (**1**, **2** and **3**) are less stable than pristine  $C_{60}$  under electron beam irradiation.

**Figure 2.** HR-TEM images of (a)  $C_{60}$ @SWNTs, (b) 1@SWNTs, (c) 2@SWNTs, and (d) 3@SWNTs.

The Raman spectroscopic characterization of empty SWCNT,  $C_{60}$ @SWCNT, 1@SWCNT, 2@SWCNT, and 3@SWCNT peapods is carried out to study the interactions between the fullerene moieties and SWCNTs. It is obvious that the encapsulation of these  $C_{60}$ -molecules does not cause any additional structural damage to the nanotubes because of the nearly identical intensity of the D bands ( $1342\text{ cm}^{-1}$ ) for the above four samples (Figure 3a). In addition, there is a slight broadening of the G-bands ( $1572\text{ cm}^{-1}$ ) of the doped nanotubes (Figure S9), especially in  $C_{60}$ @SWCNTs and 1@SWNTs, which further confirms the high filling ratio and strong interactions between the dopants and SWCNTs [26].

**Figure 3.** Raman spectra of the  $C_{60}$ @SWCNT, 1@SWCNT, 2@SWCNT, and 3@SWCNT peapods and empty SWCNTs in the ranges of (a)  $1300\text{--}1800\text{ cm}^{-1}$  (D bands and G bands) and (b)  $50\text{--}400\text{ cm}^{-1}$  (RBM bands). The Raman spectra were obtained with an excitation wavelength of  $532\text{ nm}$ , at room temperature.

The Raman results in the radial-breathing-mode (RBM) region reveal that the mutual interactions between fullerene moieties and SWCNTs are highly diameter-selective in the samples under study (Figure 3b and Table 1) [27]. The un-doped SWCNTs display typical RBM peaks corresponding to the diameters of  $1.89\text{ nm}$ ,  $1.65\text{ nm}$ , and  $1.35\text{ nm}$ , respectively. After encapsulation, the peaks corresponding to the samples with a diameter of either  $\sim 1.89\text{ nm}$  or  $\sim 1.65\text{ nm}$  are unchanged, indicating that the encapsulation of  $C_{60}$ , 1, 2 and 3 does not affect strongly the vibrations of these large nanotubes because of weak inter-outer interactions. We can, thus, speculate that the effect of the suppression between the encapsulated fullerenes and SWCNTs is probably the major reason for the unchanged resonant condition of the doped SWCNTs. However, the peak at  $183\text{ cm}^{-1}$ , corresponding to a diameter of  $1.35\text{ nm}$  for the pristine SWCNTs, is obviously shifted for the doped

samples. To expand, a new peak at  $172\text{ cm}^{-1}$  (1.44 nm) is observed for  $\text{C}_{60}$ @SWCNTs, and new peaks in a range from  $175\text{ cm}^{-1}$  (1.42 nm) to  $191\text{ cm}^{-1}$  (1.27 nm) are found for another three peapods. According to the relevant research, it is customary to assess the successful formation of peapods by scrutinizing the emergence of distinct signals within the Raman spectra of the peapod systems [28,29]. These results clearly confirm the diameter-selective interactions between the fullerene derivatives and SWCNTs. In particular, the appearance of RBM peaks corresponding to a diameter of about 1.40 nm is attributed to interactions between the SWCNTs and the encapsulated fullerenes ( $\text{C}_{60}$ , 1, 2 and 3) inside the nanotubes, while the interactions between SWCNTs and the functionalized fullerenes attached to the outer surfaces of nanotubes lead to the appearance of RBM peaks corresponding to a diameter below 1.30 nm. The appearance of these new RBM peaks provides strong evidence of the diameter-selective interactions between SWCNTs and the functionalized fullerenes inside and outside the nanotubes [30].

**Table 1.** The positions of the RBM peaks for the SWCNTs before and after the encapsulation of  $\text{C}_{60}$ , 1, 2 and 3 (the values in parentheses are the diameters of the corresponding tubes, calculated via the RBM peaks, using the equation  $D\text{ (nm)} = 248/\omega$ ).

Samples	The RBM Peaks ( $\text{cm}^{-1}$ ) and Calculated Diameters (nm) of the SWCNTs				
SWCNT	131.22 (1.89)	150.30 (1.65)		183.70 (1.35)	
$\text{C}_{60}$ @SWCNT	131.22 (1.89)	152.15 (1.63)	172.22 (1.44)	183.70 (1.35)	
1@SWCNT	131.22 (1.89)	151.22 (1.64)	178.42 (1.39)		195.28 (1.27)
2@SWCNT	131.22 (1.89)	162.22 (1.64)	174.64 (1.42)		190.77 (1.30)
3@SWCNT	131.22 (1.89)	149.40 (1.66)		181.02 (1.37)	195.28 (1.27)

The UV-Vis-NIR spectroscopic results for the empty SWCNTs,  $\text{C}_{60}$ @SWCNTs, 1@SWCNTs, 2@SWCNTs, and 3@SWCNTs, together with the corresponding precursors ( $\text{C}_{60}$ , 1, 2 and 3), are shown in Figure 4 (Figures S8 and S10–S12), to allow further investigation of the inner-outer interactions. The precursors ( $\text{C}_{60}$ , 1, 2 and 3) dissolved in  $\text{CS}_2$  display strong bands at around 330 nm, with a characteristic absorption peak at about 430 nm for the [6,6]-addition patterns in 1, 2 and 3 [13,31]. However, these characteristic peaks disappear completely after encapsulation inside nanotubes, indicating a shielding effect of the  $\pi$ -system of SWCNTs on the absorption of fullerene derivatives. Upon encapsulating fullerene derivatives, the peapods exhibit a significant broadening of approximately  $\sim 13\text{ nm}$  and a blue shift of approximately  $\sim 10\text{ nm}$  at the absorption band of 300–400 nm, compared to pristine SWCNTs (Figure 4b), suggesting that the encapsulated fullerenes have an obvious influence on the electronic structure of the SWCNTs.

**Figure 4.** UV-Vis absorption spectra of (a)  $\text{C}_{60}$ , 1, 2 and 3 dissolved in  $\text{CS}_2$ ; (b) 1@SWCNTs, 2@SWCNTs, 3@SWCNTs,  $\text{C}_{60}$ @SWCNTs, and empty SWCNTs dispersed in ethanol.

### 3. Materials and Methods

#### 3.1. Purification of SWCNTs

The deuterated chloroform (99.8%) was supplied by J&K Chemical Limited. The other chemicals and solvents were purchased from Sinopharm Chemical Reagent Co., Ltd. All the chemicals and reagents were used without further purification.

The SWCNT samples, with a purity of 75 wt%, were supplied by OCSiAl Ltd. The as-received SWCNT samples were heated at 350 °C in air for 30 min, and then were refluxed in a mixed solution of  $K_2S_2O_8$  (0.2 mol/L) and sulfuric acid (98%), with a volume ratio of 6:1, at 60 °C for 24 h. The resulting samples were washed with hydrochloric acid to further remove metal impurities. The high purity over 90% of the resulting SWCNTs was verified via TGA and Raman spectra (Figure S1a,b). The diameter distribution of the SWCNTs was estimated to be in the range of 1.27 nm–2.05 nm via Raman spectroscopy and HR-TEM observation. The oxidation treatment opened the ends and led to some defects along the walls of the SWCNTs, which guaranteed sufficient entrances and facilitated the encapsulation process of the fullerene derivatives. However, the exposed nanotube ends were also functionalized with carboxylic groups to go against the efficient encapsulation of fullerenes [32,33], which should be eliminated prior to the encapsulation process. To this end, the purified SWCNTs were conducted with a heat treatment at 500 °C for 30 min in air to ensure sufficient holes and the decomposition of carboxylic groups. The resulting SWCNTs were kept at 120 °C to get rid of water and were taken out immediately prior to the encapsulation process.

#### 3.2. Synthesis of 1, 2 and 3

The fullerene derivative 1  $C_{60}(C_6H_{15}N)$  (Figures S2 and S3) was synthesized according to a previously reported procedure [31]; the fullerene derivative 2  $C_{60}(C_{12}H_{14}O_2)$ ,  $PC_{61}BM$  (>99.5%, HPLC) was purchased from Luminescence Technology Corp; the fullerene derivative 3  $C_{60}(C_{17}H_{27}NO)$  was prepared according to the procedure outlined in Scheme 1.

**Scheme 1.** The synthetic procedure for derivative 3.

To explain further, a solution of  $C_{60}$  (720 mg, 1 mmol) (Figures S6 and S7) in 150 mL chlorobenzene was mixed with 4-(octyloxy) benzaldehyde (936 mg, 4 mmol) and sarcosine (268 mg, 3 mmol) in 20 mL chlorobenzene, and the reaction mixture was heated at 120 °C under an argon atmosphere. The whole reaction process was monitored via HPLC (Figure S4). In the beginning, the two peaks corresponding to the solvent and  $C_{60}$  appeared at 4.3 min and 7.9 min, respectively, indicating that no reaction had taken place. After 60 min, the peak of the desired product 3 appeared at 4.7 min, and the peak intensity continued to increase along with the increasing reaction time. The reaction was terminated after 300 min revealing a significant increase in the intensity of the product peak, accompanied by a notable attenuation of the starting material peak. Simultaneously, peaks indicative of bis- or multi-adducts were observed. Finally, the reaction mixture was separated via HPLC, which gave 3 (Figure S5) in a yield of 68% based on the consumed  $C_{60}$ .

#### 3.3. Characterizations

High-resolution transmission electron microscopy (HR-TEM) observations were performed with a FEI Tecnai G2F20 S-TWIN at an acceleration voltage of 200 kV. The imaging conditions were set to minimize the irradiation damage as much as possible. The specimens

were suspended in ethanol (99.9 vol.%) via sonication and then dropped onto a copper microgrid. Raman spectra were collected using a LabRAM HR800 spectrometer and measured via random selection with a laser excitation wavelength of 532 nm in ambient conditions. The suspensions of peapods in ethanol were added dropwise onto the microslide, resulting in film samples. UV-visible-near-infrared (UV-Vis-NIR) spectra were recorded using a PE Lambda 750S spectrophotometer, with a wavelength range of 300–800 nm for the fullerenes and their derivatives dissolved in CS<sub>2</sub>, and of 300–2000 nm for the empty and doped SWCNTs dispersed in ethanol (the results for the peapods dispersed into D<sub>2</sub>O with surfactants such as sodium cholate, sodium deoxycholate, and sodium dodecylbenzenesulfonate were quite similar to those for ethanol). The isolation of C<sub>60</sub> and its derivatives was conducted via preparative high-performance liquid chromatography (HPLC) with an LC-9130 NEXT instrument, using toluene as an eluent. MALDI-TOF mass spectra were measured using a BIFLEX III spectrometer, with 1,1,4,4-tetraphenyl-1,3-butadiene as the matrix. <sup>1</sup>H and <sup>13</sup>C NMR spectra were recorded in deuterated chloroform at 600 MHz and 151 MHz, respectively. Chemical shifts ( $\delta$ ) were given in ppm relative to the solvent, and the coupling constants (J) were given in Hz. Thermal gravimetric analysis (TGA) was performed under air flow from the ambient temperature to 800 °C, at a heating rate of 10 °C/min.

#### 4. Conclusions

In conclusion, we successfully encapsulated C<sub>60</sub> and its three derivatives into SWCNTs to obtain the corresponding peapod structures. Our findings indicate that the filling ratio of peapods evidently relies on the steric bulk of the functional group of the derivatives. Moreover, Raman spectroscopic characterizations illuminate that the selective appearance of the RBM peaks of the doped SWCNTs is clearly associated with the diameter-selective interactions between SWCNTs and the functionalized fullerenes both inside and outside nanotubes. It is further confirmed that the encapsulation of functionalized fullerenes directly affects the electronic structure of SWCNTs via UV-Vis-NIR absorption spectra. Our study exposes the relationship of the interactions between the functionalized fullerenes and SWCNTs in hybrid peapod structures. We expect that the insights gained in this investigation may provide future theoretical works for designing controllable synthesis of, and good properties in, nano peapods. Our results have shed new light on the controlled synthesis and property-tuning of nano peapods.
