Estimation of enhancement factor

To examine the enhancement factor (EF) of prepared SERS substrates, 4-Mercaphenol commonly used SERS molecules were measured. The SERS EF is a quantitative measure of the Raman signal amplification of the analyte. The EF value using the reported protocol. The EF can be calculated by:

$$EF = \frac{I_{SERS} N_{Ref}}{I_{Ref} N_{SERS}} \quad (S1)$$

Where N_{SERS} and N_{Ref} are the number of molecules probed on the Ag-NPs @PAN-nanohump array film and on the reference sample, respectively. I_{SERS} and I_{Ref} correspond to SERS signal and un-enhanced normal signals intensities, respectively. Herein, a certain volume (V_{SERS}) and concentration (C_{SERS}) 4-Mercaptophenol ethanol solution was dispersed to an area of S_{SERS} at the Ag-NPs @PAN-nanohump array film substrate. For non-SERS Raman spectra, a certain volume (V_{Ref}) and concentration (C_{Ref}) 4-Mercaphenol ethanol solution was dispersed to an area of S_{Ref} at a clean Si substrate. Both the substrates were dried in the air. Considering the area of laser spot is the same, the foregoing equation thus becomes:

$$EF = \frac{I_{SERS}}{I_{Ref}} \cdot \frac{C_{Ref} V_{Ref}}{C_{SERS} V_{SERS}} \cdot \frac{S_{SERS}}{S_{Ref}} \quad (S2)$$

In this experiment, 2.5 μ L of 1 $\times 10^{-9}$ M 4-Mercaphenol ethanol solution was dispersed to an area of 36mm² for the Ag-NPs @PAN-nanohump array film substrate and 2.5 μ L of 1 $\times 10^{-3}$ M 4-

Mercapphenol ethanol solution was dispersed to an area of 20mm² for the silicon wafer. For the band at 1078cm⁻¹, ISERS/IRef was 11107/1815=6.12 There is average enhancement factor for the band at 1078cm⁻¹ is calculated to be 1.1×10⁷.

Figure S1. (a) SERS spectrum of 2.5μL of 1×10⁻⁶M 4-Mercapphenol ethanol solution was dispersed to an area of 36 mm² for the Ag-NPs @PAN-nano-hump array film. (b). Raman spectrum of 2.5μL of 1×10⁻³M 4-Mercapphenol ethanol solution was dispersed to an area of 20mm² for the silicon wafer. The exposure time was 60s.

(g) the distributions of selected variables for the BOSS-PLS built model; (h) BOSS-PLS model results.

The stability of the system

To examine stability of the method, Ag-NPs @PAN-nanohump array film stored for a certain period was used to detect the carbendazim at concentrations of 0.1, 0.5, 1, 5, 10 mg L⁻¹. As displayed in Fig. S3 the detection results of Ag-NPs @PAN-nano-hump array film after different storage days (0, 1, 3, 5, 7, 14 d) remained unchanged, which proved that the prepared Ag-NPs @PAN-nanohump array film has good stability.

Figure S3. The stability of the system.
