**Abstract:** Novel  $(80\text{Li}_2\text{S} - 20\text{AlI}_3) \cdot y\text{LiI}$  composite solid electrolytes ( $y = 5, 10, 15$ ) were prepared by mechanochemical synthesis. XRD results showed that the pattern of  $80\text{Li}_2\text{S} - 20\text{AlI}_3$  was similar to that of  $\text{AlI}_3$ , which means that  $\text{Li}_2\text{S}$  was dissolved in  $\text{AlI}_3$  matrix during preparation. This structure was still maintained after LiI addition. The current measured at constant applied DC voltage indicated that  $(80\text{Li}_2\text{S} - 20\text{AlI}_3) \cdot y\text{LiI}$  composites are intrinsically pure Li-ion conductors. The ionic conductivity at 25 °C of  $y = 10$  was about  $2.3 \times 10^{-4} \text{ Scm}^{-1}$ , which was about three times higher than that of  $y = 0$ . The conductivity of  $y = 10$  increased 20 times to  $2.2 \times 10^{-3} \text{ Scm}^{-1}$  at 70 °C. These values were highest among those observed from  $\text{Li}_2\text{S}$ -based materials. It was revealed that Li-ion moves in  $80\text{Li}_2\text{S} - 20\text{AlI}_3$  by a hopping mechanism, while the lattice dipoles are the origin of Li-ion movement in  $(80\text{Li}_2\text{S} - 20\text{AlI}_3) \cdot y\text{LiI}$ . The polarization measurements using  $\text{LiI}90 (80\text{Li}_2\text{S} - 20\text{AlI}_3) \cdot 10\text{LiI}$  and  $\text{LiI}90 (80\text{Li}_2\text{S} - 20\text{AlI}_3) \cdot 10\text{LiI}$  cells proved that 90  $(80\text{Li}_2\text{S} - 20\text{AlI}_3) \cdot 10\text{LiI}$  reacts with Li metal, but it is relatively stable at a low voltage. Sample  $y = 10$  was also employed as a solid electrolyte in the positive electrode of a solid-state Li-S battery to study its stability in the voltage range of the positive electrode.  $\text{CuS}$  and  $\text{Li}_{4.4}\text{Si}$  were the electrode-active materials. The cell was cycled in CC-CV mode at 1.0 mA  $\text{cm}^{-2}$  (CC) with a cut-off voltage of 1.0–2.3 V. The cell delivered a stable capacity of about 400 mAh  $\text{g}^{-1}_{\text{CuS}}$  after 40 cycles.

## 1. Introduction

Sulfide-based solid electrolytes (SEs) are one of the candidates for all-solid-state (ASS) Li-ion batteries due to their high ionic conductivity at room temperature and suitable mechanical properties [1–3].  $\text{Li}_7\text{P}_3\text{S}_{11}$ ,  $\text{Li}_{10}\text{GeP}_2\text{S}_{12}$ , and  $\text{Li}_{5.5}\text{PS}_{4.5}\text{Cl}_{1.5}$  exhibited ionic conductivity higher than  $10^{-2} \text{ Scm}^{-1}$  at 25 °C [4–6]. Sulfide-based solid electrolytes can be prepared using different methods: solid-state reaction at high temperature, mechano-synthesis, and liquid phase synthesis [7–9]. Until now, most of the reported sulfide-based solid electrolytes have belonged to  $\text{Li}_2\text{S}-\text{P}_2\text{S}_5\text{-LiX}$  ( $X = \text{halogen}$ ) groups; therefore, the search for sulfide-based electrolytes that do not contain  $\text{P}_2\text{S}_5$  is an interesting research direction.

The glass and glass-ceramic electrolytes of the  $(100 - x)\text{Li}_2\text{S} \cdot x\text{Al}_2\text{S}_3$  group were synthesized using planetary ball milling and thoroughly studied [10]. Amorphous  $60\text{Li}_2\text{S} \cdot 40\text{AlS}_{1.5}$  was obtained with a milling speed of 230 rpm, while glass-ceramic containing  $\text{Li}_5\text{AlS}_4$  crystal was directly obtained with a milling speed of 510 rpm for 2 h. The highest conductivity of  $3.4 \times 10^{-5} \text{ Scm}^{-1}$  at 25 °C was obtained for the  $60\text{Li}_2\text{S} \cdot 40\text{AlS}_{1.5}$  amorphous electrolytes.  $\text{Li}_2\text{S}-\text{SiS}_2$  and  $\text{Li}_3\text{PO}_4\text{-Li}_2\text{S}-\text{SiS}_2$  glassy SEs were also prepared by the melt-quenching method, and their ionic conductivities and electrochemical properties were investigated [11,12]. The highest conductivity, of about  $7.6 \times 10^{-4} \text{ Scm}^{-1}$  at 25 °C, was obtained in those systems. The solid-state cell using graphite as active material and

$0.03\text{Li}_3\text{PO}_4\text{-}0.58\text{Li}_2\text{S}\text{-}0.39\text{SiS}_2$  as solid electrolyte showed good cycle performance. On the other hand,  $\text{Li}_2\text{S}\text{-SiS}_2$  amorphous materials were also prepared by mechanochemical synthesis and showed the highest conductivity of about  $3.4 \times 10^{-4} \text{ Scm}^{-1}$  at  $25^\circ\text{C}$  [13].

$\text{Li}_2\text{S}$  has been intensively used as positive electrode material in the Li-S battery because its usage enables the employment of graphite or silicon in the negative electrode. However,  $\text{Li}_2\text{S}$  is a natural insulator to both electrons and ions; much effort has been made to increase the electron and ionic conductivity of  $\text{Li}_2\text{S}$ . Fabricating composites with carbonaceous materials, such as graphene, carbon nanotubes, or carbon nanofibers, will increase the electronic conductivity of  $\text{Li}_2\text{S}$  [14–17]. On the other hand, many other methods for increasing the ionic conductivity of  $\text{Li}_2\text{S}$  have been reported so far. Composite nanoparticles with  $\text{Li}_2\text{S}$  as the core and  $\text{Li}_3\text{PS}_4$  as the shell exhibit ionic conductivity of about  $10^{-7} \text{ Scm}^{-1}$  at  $25^\circ\text{C}$ , which is  $10^4$  times higher than that of  $\text{Li}_2\text{S}$  nanoparticles [18]. The ionic conductivity of  $\text{Li}_2\text{S}\text{-Li}_3\text{PS}_4$  reaches  $10^{-4} \text{ Scm}^{-1}$  at  $25^\circ\text{C}$  in another report [19]. The ionic conductivity of  $\text{Li}_2\text{S}\text{-LiX}$  solid solution ( $\text{X} = \text{halogen}$ ) is about  $10^{-6} \text{ Scm}^{-1}$ , which is about  $10^2$  times higher than that of  $\text{Li}_2\text{S}$  [20]. Solid solutions of  $\text{Li}_2\text{S}$  and multivalence cation sulfides,  $\text{Li}_{2-2x}\text{Mg}_x\text{S}$  ( $0.05 \leq x \leq 0.2$ ) and  $\text{Li}_{2-3x}\text{Al}_x\text{S}$  ( $0 \leq x \leq 0.1667$ ), also show improved ionic conductivity compared with  $\text{Li}_2\text{S}$  [21,22]. The ionic conductivity of  $80\text{Li}_2\text{S}\text{-}20\text{AlI}_3$  even reaches  $6.0 \times 10^{-5} \text{ Scm}^{-1}$  at  $25^\circ\text{C}$  [23]. In the same study,  $99.5\text{Li}_2\text{S}\text{-}0.5\text{AlI}_3$  acted as both SE and active material in an all-solid-state battery. In addition, antiperovskite-like type  $\text{Li}_3\text{SI}$  had an ionic conductivity of  $2.2 \times 10^{-5} \text{ Scm}^{-1}$  at  $25^\circ\text{C}$  and was employed as SE in the ASS Li-ion battery [24]. It should be noted that the application of  $\text{Li}_2\text{S}$ -based as SE in the ASS battery is very rare due to its low ionic conductivity.

In this study, a series of  $(100 - x)\text{Li}_2\text{S}\text{-}x\text{AlI}_3$  and  $(80\text{Li}_2\text{S} - 20\text{AlI}_3)\cdot y\text{LiI}$  composite solid electrolytes ( $y = 5, 10, 15$ ) were prepared by mechanochemical synthesis and investigated using XRD and AC impedance spectroscopy. The ionic conductivity at  $25^\circ\text{C}$  ( $80\text{Li}_2\text{S} - 20\text{AlI}_3$ ) $\cdot y\text{LiI}$  ( $y = 5, 10, 15$ ) is higher than that of  $80\text{Li}_2\text{S}\text{-}20\text{AlI}_3$  and  $\text{Li}_3\text{SI}$  because LiI addition reduces the resistance at the grain boundary and interface; to the best of our knowledge, such effects of LiI have not been reported before. Among them, sample  $(80\text{Li}_2\text{S} - 20\text{AlI}_3)\cdot 10\text{LiI}$  has the highest ionic conductivity, which is about  $2.3 \times 10^{-4} \text{ Scm}^{-1}$  at  $25^\circ\text{C}$ . In addition, the complex conductivity suggested the formation of a composite consisting of  $80\text{Li}_2\text{S} - 20\text{AlI}_3$  and LiI rather than a solid solution due to the existence of two slopes in the low-frequency region. The use of complex conductivity to differentiate solid solutions from composites has also not been noted before. The electronic conductivity of  $(80\text{Li}_2\text{S} - 20\text{AlI}_3)\cdot 10\text{LiI}$  is about  $1.1 \times 10^{-8} \text{ Scm}^{-1}$ ; therefore,  $(80\text{Li}_2\text{S} - 20\text{AlI}_3)\cdot 10\text{LiI}$  is a pure Li-ion conductor. The solid-state cell, which employs CuS as active material and  $(80\text{Li}_2\text{S} - 20\text{AlI}_3)\cdot 10\text{LiI}$  as solid electrolyte, delivers a stable capacity after 40 cycles.

## 2. Experimental

$\text{Li}_2\text{S}$  (99.9%), LiCl (99.9%),  $\text{AlI}_3$  (99.9%), Si (99.99%), Li metal (99.99%), CuS (99.9%), and LiI (99.9%) were purchased from Sigma.  $\text{P}_2\text{S}_5$  (99%) was purchased from Merck Group. All chemicals were used without purification.

$(100 - x)\text{Li}_2\text{S}\text{-}x\text{AlI}_3$  and  $(80\text{Li}_2\text{S} - 20\text{AlI}_3)\cdot y\text{LiI}$  composite solid electrolytes ( $y = 5, 10, 15$ ) were prepared via planetary ball milling using the same conditions as reported previously [23]. For a typical batch,  $\text{Li}_2\text{S}$ ,  $\text{AlI}_3$ , and LiI were manually mixed for 10 min prior to introduction into 45 mL zirconia pots with zirconia balls (10 mm, 15 balls). The pots were then rotated at 500 rpm for 12 h using a Pulverisette 7 (Fritsch). The obtained samples were recovered and used without any further heat treatment.  $\text{Li}_{4.4}\text{Si}$  was prepared using the procedure reported by Tamori et al. [25]. A total of 0.7814 g Li and 0.7186 g Si (Li:Si = 4.4:1.0 mole ratio) was manually mixed using an agate mortar for about 15 min; the obtained mixture was then introduced into 45 mL zirconia pots with zirconia balls (4 mm, 10 balls). The pots were then rotated at 200 rpm. For one cycle, 10 min milling time and 5 min resting time was employed to avoid the sample from temperature increasing.  $\text{Li}_{4.4}\text{Si}$  was recovered after 50 h of milling time.  $\text{Li}_6\text{PS}_5\text{Cl}$  was prepared using the same method. In a typical batch, 2 g of  $\text{Li}_2\text{S}$ ,  $\text{P}_2\text{S}_5$ , and LiCl with a stoichiometric ratio of 5:1:2

was employed. The raw materials were manually mixed for 10 min prior to introduction into 45 mL zirconia pots with zirconia balls (10 mm, 10 balls). A rotation speed of 600 rpm and a rotation time of 20 h were employed.

XRD patterns were recorded using Bruker X8 with a  $\text{CuK}\alpha$  radiation. The samples were covered with amorphous Kapton film because of their hygroscopic properties.

The total resistivity of the prepared samples was investigated using AC impedance spectroscopy, as reported previously [26]. DC conduction was recorded using stainless steel (SUS) rods as blocking electrodes and lithium metal sheets as non-blocking electrodes. Prior to the measurements, the sample  $(80\text{Li}_2\text{S} - 20\text{AlI}_3) \cdot 10\text{LiI}$  was made into pellets of about 10 mm in diameter (550 MPa, at RT). Since the sample  $(80\text{Li}_2\text{S} - 20\text{AlI}_3) \cdot 10\text{LiI}$  continuously reacts with Li metal, a thin layer of  $\text{Li}_6\text{PS}_5\text{Cl}$  solid electrolyte was introduced to the cell to prevent  $(80\text{Li}_2\text{S} - 20\text{AlI}_3) \cdot 10\text{LiI}$  from direct contact with Li metal. Two SUS rods were employed as current collectors. The currents were measured using a potentiostat (PGSTAT302N, Autolab, Herisau, Switzerland) with applied voltages of 0.2–0.7 V (DC) for 60 min.

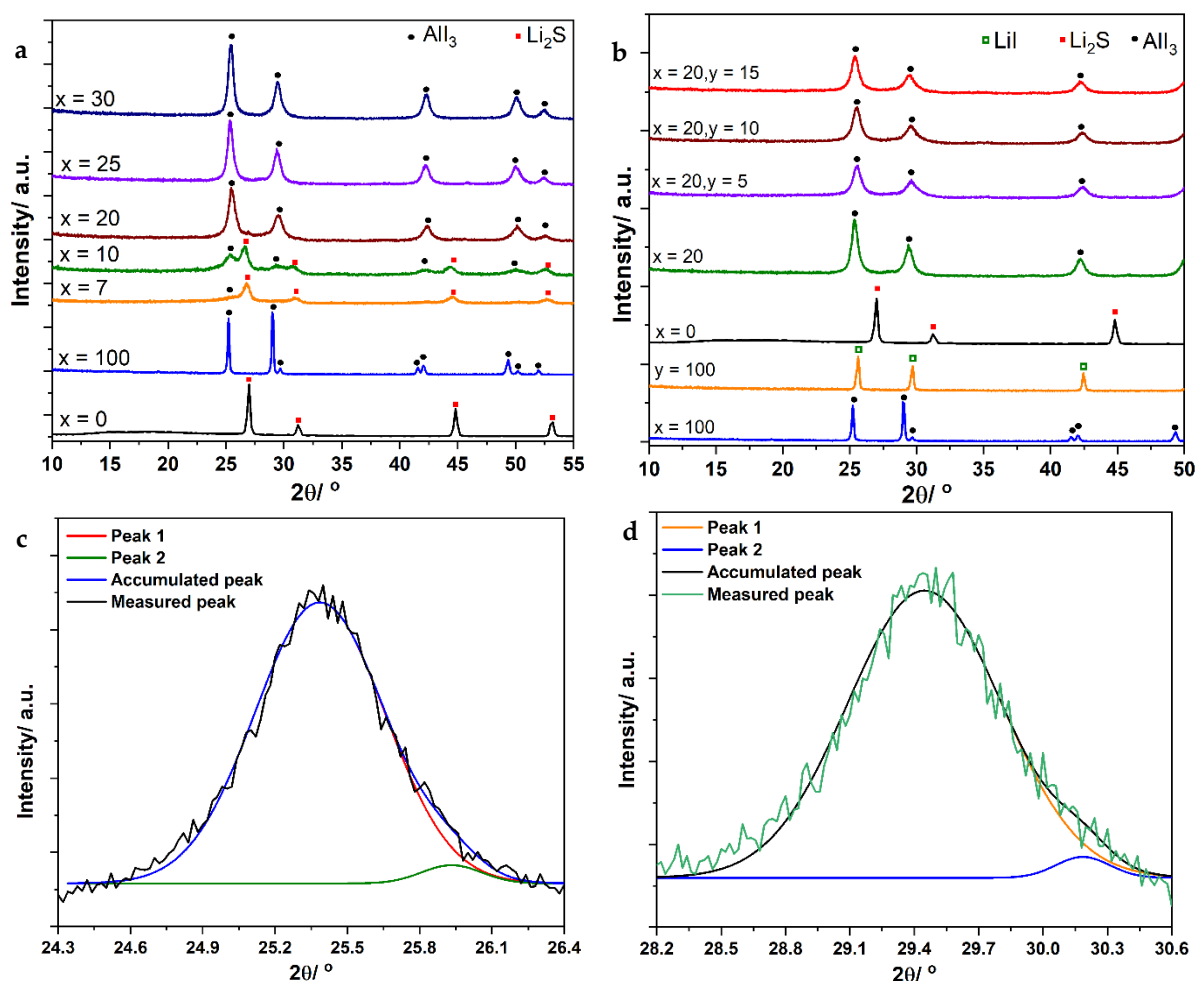

DC polarization curves were recorded using the cell  $\text{LiI}|\text{Li}_6\text{PS}_5\text{Cl}||(\text{80Li}_2\text{S} - 20\text{AlI}_3) \cdot 10\text{LiI}|\text{Li}$  cycling at  $\pm 0.05$ ,  $\pm 0.1$ , and  $\pm 0.2 \text{ mA cm}^{-1}$  [27].

Two-step planetary ball milling was used to prepare the composite cathode. In total, 0.3 g of CuS and Ketjen Black (weight ratio of 4:1) were mixed in zirconia pots using 30 g of zirconia balls (4 mm) at 410 rpm for 10 h. Then, 0.2 g of  $(80\text{Li}_2\text{S} - 20\text{AlI}_3) \cdot 10\text{LiI}$  was added, and the positive electrode composites were obtained after 2 h mixing at 300 rpm. The ASS Li-S cell was constructed as previously reported using the prepared electrode composite,  $\text{Li}_6\text{PS}_5\text{Cl}$ , and  $\text{Li}_{4.4}\text{Si}$  [26]. The cells were cycled using either CC or CC-CV mode to study the stability of  $(80\text{Li}_2\text{S} - 20\text{AlI}_3) \cdot 10\text{LiI}$  at a high voltage range. The current density was  $0.25 \text{ mA cm}^{-2}$ .

All the experiments were carried out in a glove box (Ar-filled,  $[\text{H}_2\text{O}] < 0.1 \text{ ppm}$ ) or an airtight sample holder.

### 3. Results and Discussion

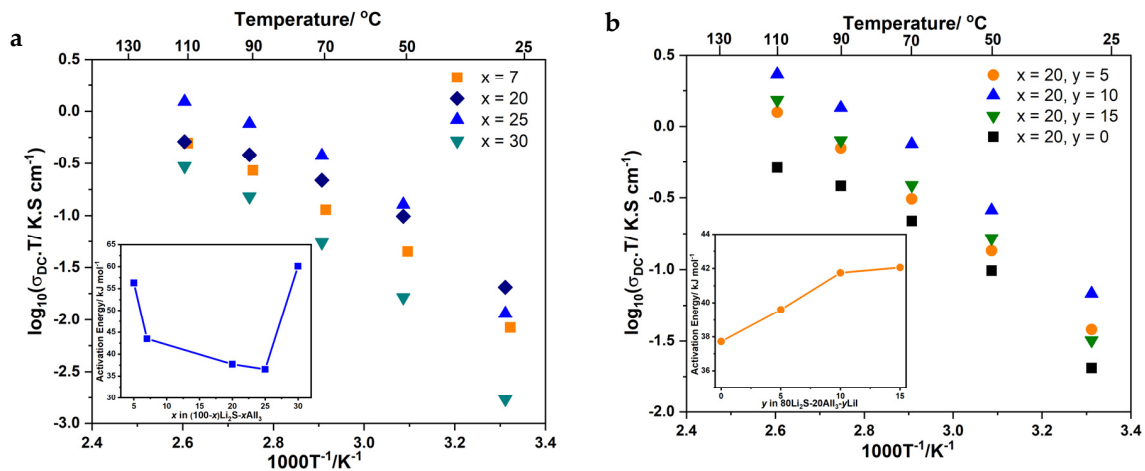

Figure 1 shows the XRD patterns of  $(100 - x)\text{Li}_2\text{S} - x\text{AlI}_3$  (Figure 1a) and  $(80\text{Li}_2\text{S} - 20\text{AlI}_3) \cdot y\text{LiI}$  (Figure 1b) composite solid electrolytes ( $y = 5, 10, 15$ ). Sample  $\text{Li}_2\text{S}$  ( $x = 0$ ) was characterized by four intense peaks located at  $2\theta \approx 27.03, 31.22, 44.77, \text{ and } 53.15^\circ$ . The pattern of  $\text{AlI}_3$  ( $x = 100$ ) has two intense peaks at  $2\theta \approx 25.24 \text{ and } 29.06^\circ$ . Samples  $x = 7$  and  $x = 10$  exhibited characteristic peaks of both  $\text{Li}_2\text{S}$  and  $\text{AlI}_3$ ; however, the features of  $\text{AlI}_3$  were more clearly observed in sample  $x = 10$  than in sample  $x = 7$ . The features of  $\text{Li}_2\text{S}$  disappeared in the samples  $x = 20, 25, \text{ and } 30$ , indicating that  $\text{Li}_2\text{S}$  became amorphous or a new crystal structure was formed because the XRD pattern of those samples did not completely cover  $\text{AlI}_3$  peaks. It was also proved that samples  $5 \geq x \geq 0$  exhibited the crystal structure of  $\text{Li}_2\text{S}$  [23]. Therefore,  $(100 - x)\text{Li}_2\text{S} - x\text{AlI}_3$  exhibits the structure of  $\text{Li}_2\text{S}$  when  $5 \geq x \geq 0$  and the structure of  $\text{AlI}_3$  when  $x \geq 20$ ; those results also show that the  $(100 - x)\text{Li}_2\text{S} - x\text{AlI}_3$  solid solution can be prepared by mechanochemical synthesis, and its structure depends on the  $\text{Li}_2\text{S}$  mass fraction. XRD patterns of  $(80\text{Li}_2\text{S} - 20\text{AlI}_3) \cdot y\text{LiI}$  composites and raw materials are illustrated in Figure 1b. The  $(80\text{Li}_2\text{S} - 20\text{AlI}_3) \cdot y\text{LiI}$  composites exhibited the characteristic peaks of  $\text{AlI}_3$  and no trace of  $\text{LiI}$  ( $y = 100$ ) was detected. However, fitting the pattern of sample  $y = 15$  disclosed that the peak at  $25.4^\circ$  is composed of two peaks at  $25.4$  and  $25.9^\circ$ , and the peak at  $29.4^\circ$  is composed of two peaks at  $29.4$  and  $30.2^\circ$  (Figure 1c,d). Those fitting results proved that  $\text{LiI}$  crystal still remained in sample  $y = 15$ , while its existence in  $y = 5$  and  $10$  was not detected. Therefore,  $\text{LiI}$  might form a solid solution with  $80\text{Li}_2\text{S} - 20\text{AlI}_3$  or it exists in the amorphous form in samples  $y = 5$  and  $10$ .

**Figure 1.** XRD patterns of the prepared samples. (a) XRD patterns of  $(100 - x)\text{Li}_2\text{S} - x\text{AlI}_3$ ; (b) XRD patterns of  $(80\text{Li}_2\text{S} - 20\text{AlI}_3) \cdot y\text{LiI}$  ( $y = 0, 5, 10, 15$ ); (c,d) Fitting result of peak at  $25.4^\circ$  and  $29.4^\circ$  of sample  $y = 15$ , respectively.

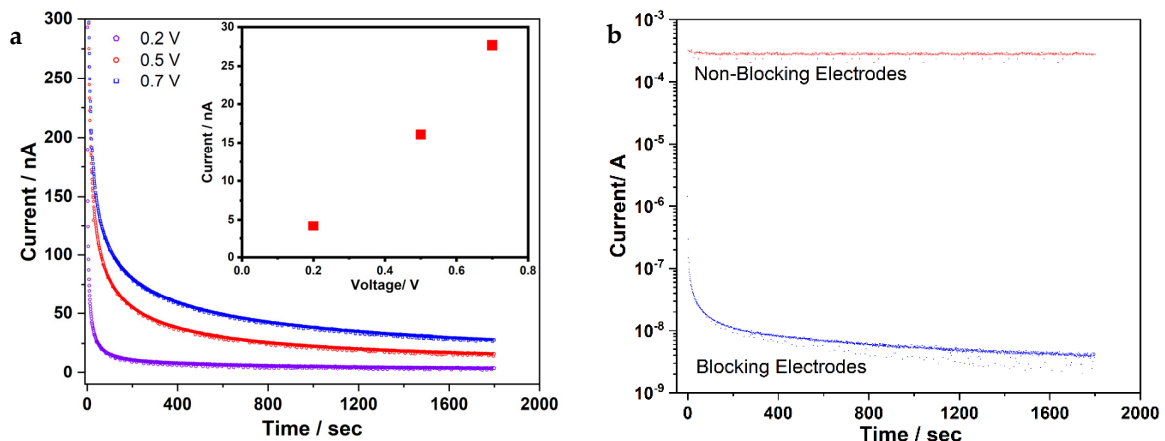

Figure 2 shows the temperature dependence of the ionic conductivity of  $(100 - x)\text{Li}_2\text{S} - x\text{AlI}_3$  (Figure 2a) and  $(80\text{Li}_2\text{S} - 20\text{AlI}_3) \cdot y\text{LiI}$  (Figure 2b) composite solid electrolytes ( $y = 5, 10, 15$ ). The small insets show the activation energy of the samples. The ionic conductivity of  $\text{Li}_2\text{S}$  at  $25^\circ\text{C}$  was about  $10^{-12} \text{Scm}^{-1}$  [18,23]. Sample  $x = 7$  exhibited ionic conductivity at  $25^\circ\text{C}$  of about  $2.8 \times 10^{-5} \text{Scm}^{-1}$ . Samples  $x = 20, 25,$  and  $30$  had ionic conductivity at  $25^\circ\text{C}$  of about  $5.8 \times 10^{-5} \text{Scm}^{-1}, 3.8 \times 10^{-5} \text{Scm}^{-1},$  and  $3.1 \times 10^{-5} \text{Scm}^{-1}$ , respectively. The activation energy of sample  $x = 5, 7, 20, 25,$  and  $30$  was about  $56, 44, 38, 37,$  and  $60 \text{kJ mol}^{-1}$ . The activation energy of the samples decreased when  $x$  increased and reached the minima values of about  $38 \text{kJ mol}^{-1}$  in samples  $x = 20, 25$ . Thus, forming a solid solution with  $\text{AlI}_3$  could enhance the ionic conductivity of  $\text{Li}_2\text{S}$ , but the ionic conductivity of  $(100 - x)\text{Li}_2\text{S} - x\text{AlI}_3$  at  $25^\circ\text{C}$  was still lower than  $10^{-4} \text{Scm}^{-1}$ . It was reported that the ionic conductivity of  $\text{Li}_3\text{PS}_4$  improved with  $\text{LiI}$  addition, so  $\text{LiI}$  was also added to  $80\text{Li}_2\text{S} - 20\text{AlI}_3$  to investigate the ionic conductivity improvement [28,29]. The temperature dependence of the ionic conductivity of  $(80\text{Li}_2\text{S} - 20\text{AlI}_3) \cdot y\text{LiI}$  composite solid electrolytes ( $y = 0, 5, 10, 15$ ) are shown in Figure 2b. The conductivity of  $80\text{Li}_2\text{S} - 20\text{AlI}_3$  ( $x = 20, y = 0$ ) at  $25^\circ\text{C}$  was about  $5.8 \times 10^{-5} \text{Scm}^{-1}$ ; this value increased to  $1.1 \times 10^{-4}, 2.3 \times 10^{-4},$  and  $1.0 \times 10^{-4} \text{Scm}^{-1}$ . The activation energy for the Li-ion movement was about  $38, 40, 42,$  and  $42$  in samples  $y = 0, 5, 10,$  and  $15$ , respectively. The existence of  $\text{LiI}$  crystals, as shown in Figure 1c,d, is responsible for the decrease in conductivity of sample  $y = 15$  compared with sample  $y = 10$ . Thus,  $\text{LiI}$  addition could enhance the ionic conductivity of  $80\text{Li}_2\text{S} - 20\text{AlI}_3$  and

$(80\text{Li}_2\text{S} - 20\text{AlI}_3) \cdot 10\text{LiI}$  had the highest Li-ion conductivity among the prepared sample at 25 °C.

**Figure 2.** Ionic conductivity of the prepared samples. (a) Temperature dependence of ionic conductivity of  $(100 - x)\text{Li}_2\text{S} - x\text{AlI}_3$  samples and the activation energy (small inset); (b) Temperature dependence of ionic conductivity of  $(80\text{Li}_2\text{S} - 20\text{AlI}_3) \cdot y\text{LiI}$  ( $y = 0, 5, 10, 15$ ) samples and the activation energy (small inset).

Figure 3a shows the time dependence of DC current when a voltage of 0.2, 0.5, and 0.7 V (DC) was applied to sample  $(80\text{Li}_2\text{S} - 20\text{AlI}_3) \cdot 10\text{LiI}$  using a blocking electrode. The polarization was initially observed, and then the current became nearly constant. The electronic conductivity was about  $1.1 \times 10^{-8} \text{ Scm}^{-1}$ . Since  $(80\text{Li}_2\text{S} - 20\text{AlI}_3) \cdot 10\text{LiI}$  reacts with Li metal, a thin layer of  $\text{Li}_6\text{PS}_5\text{Cl}$  was employed to prevent  $(80\text{Li}_2\text{S} - 20\text{AlI}_3) \cdot 10\text{LiI}$  from direct contact with Li metal. A constant current was obtained when 0.5 V (DC) was applied to the cell  $\text{Li}|\text{Li}_6\text{PS}_5\text{Cl}||(\text{80Li}_2\text{S} - 20\text{AlI}_3) \cdot 10\text{LiI}|\text{Li}_6\text{PS}_5\text{Cl}|\text{Li}$  (Figure 3b). The constant current obtained using the non-blocking electrode was about  $10^4$  times higher than that obtained using the blocking electrode; thus,  $(80\text{Li}_2\text{S} - 20\text{AlI}_3) \cdot 10\text{LiI}$  is considered a pure Li-ion conductor with a Li-ion transport number higher than 0.999. In addition, the ionic conductivity calculated from the current values was about  $2.1 \times 10^{-4} \text{ Scm}^{-1}$  at 25 °C, which resembled the value  $2.3 \times 10^{-4} \text{ Scm}^{-1}$  obtained from AC impedance spectroscopy.

**Figure 3.** Conductivity of  $(80\text{Li}_2\text{S} - 20\text{AlI}_3) \cdot 10\text{LiI}$ . (a) Time dependence of the conductivity at constant applied voltage of 0.2, 0.5, and 0.7 V using blocking electrodes ( $\text{SUS}|\text{80Li}_2\text{S} - 20\text{AlI}_3) \cdot 10\text{LiI}|\text{SUS}$ ); the small inset illustrates the values of constant current at each applied voltage. (b) Time dependence of the conductivity at constant applied voltage of 0.5 V using blocking electrodes ( $\text{SUS}|\text{80Li}_2\text{S} - 20\text{AlI}_3) \cdot 10\text{LiI}|\text{SUS}$ ) and non-blocking electrodes  $\text{Li}|\text{Li}_6\text{PS}_5\text{Cl}||(\text{80Li}_2\text{S} - 20\text{AlI}_3) \cdot 10\text{LiI}|\text{Li}_6\text{PS}_5\text{Cl}|\text{Li}$ .

Figure 4a,b shows the Nyquist plots of  $80\text{Li}_2\text{S} - 20\text{AlI}_3$  and  $(80\text{Li}_2\text{S} - 20\text{AlI}_3) \cdot 10\text{LiI}$  measured at 28–90 °C, respectively. All the plots consist of a semicircle and a low-frequency tail, which is consistent with  $\text{Li}^+$  blocking at the SUS electrodes, expressing ionic conductive behavior. The diameter of the semicircle gradually decreased with increasing temperature and was almost negligible at 90 °C. The total impedance value of the electrolyte pellet is the value at the intersection point between the semicircle and the x-axis in the intermediate frequency region [30]. The impedance spectra recorded at room temperature of  $80\text{Li}_2\text{S} - 20\text{AlI}_3$  and  $(80\text{Li}_2\text{S} - 20\text{AlI}_3) \cdot 10\text{LiI}$  are plotted in Figure 4c,d, respectively. The equivalence circuit of the impedance spectrum is shown in Figure 4c. The impedance resistance of  $80\text{Li}_2\text{S} - 20\text{AlI}_3$  is composed of bulk, interface, and grain boundary resistances (the color-filled regions) [31,32]. The bulk resistance of the SE ( $R_{\text{bulk}}$ ) is obtained from the intersection between the semicircle and the x-axis in the high-frequency region. The semicircle in the intermediate region is composed of interfacial resistance ( $R_{\text{Interfacial}}$ ) and grain boundary resistance ( $R_{\text{Grain boundary}}$ ). The  $R_{\text{bulk}}$  value of  $80\text{Li}_2\text{S} - 20\text{AlI}_3$  is close to that of  $(80\text{Li}_2\text{S} - 20\text{AlI}_3) \cdot 10\text{LiI}$ . While the  $R_{\text{Interfacial}} + R_{\text{Grain boundary}}$  value of  $(80\text{Li}_2\text{S} - 20\text{AlI}_3) \cdot 10\text{LiI}$  is smaller than that of  $80\text{Li}_2\text{S} - 20\text{AlI}_3$ . These results indicate that LiI addition effectively reduces the value of  $R_{\text{Interfacial}} + R_{\text{Grain boundary}}$ .

The conductivity isotherms of  $80\text{Li}_2\text{S} - 20\text{AlI}_3$  and  $(80\text{Li}_2\text{S} - 20\text{AlI}_3) \cdot 10\text{LiI}$  recorded from 28 to 90 °C, the real part  $\sigma'$  of the complex conductivity plotted against frequency  $F$ , are depicted in Figure 4e,f, respectively. The isotherms display a frequency independence plateau in high and intermediate frequency regions, which is the so-called direct current (DC) region [33,34]. This region indicates long-range ion transport. Frequency dependence of conductivity is clearly observed in the low-frequency region, which exhibits the polarization effect. Jonscher's power law  $\sigma' \propto \omega^n$  was observed in the low-frequency region, where  $\omega$  is the angular frequency and  $n$  represents the interaction between the mobile ion and its surrounding environment [35,36]. Temperature dependence of  $n$  is clearly observed in sample  $80\text{Li}_2\text{S} - 20\text{AlI}_3$  and the  $n$  values are higher than 0.6, indicating the dipole behaviors of charge carriers in this sample [36]. Two distinct slopes appear in the low-frequency region of the isotherms of sample  $(80\text{Li}_2\text{S} - 20\text{AlI}_3) \cdot 10\text{LiI}$ , with  $n$  values close to 0.7 and 0.5. The  $n$  values also indicated the dipoles behaviors of charge carriers, but the presence of two slopes suggested the existence of two types of materials in the sample  $(80\text{Li}_2\text{S} - 20\text{AlI}_3) \cdot 10\text{LiI}$ .

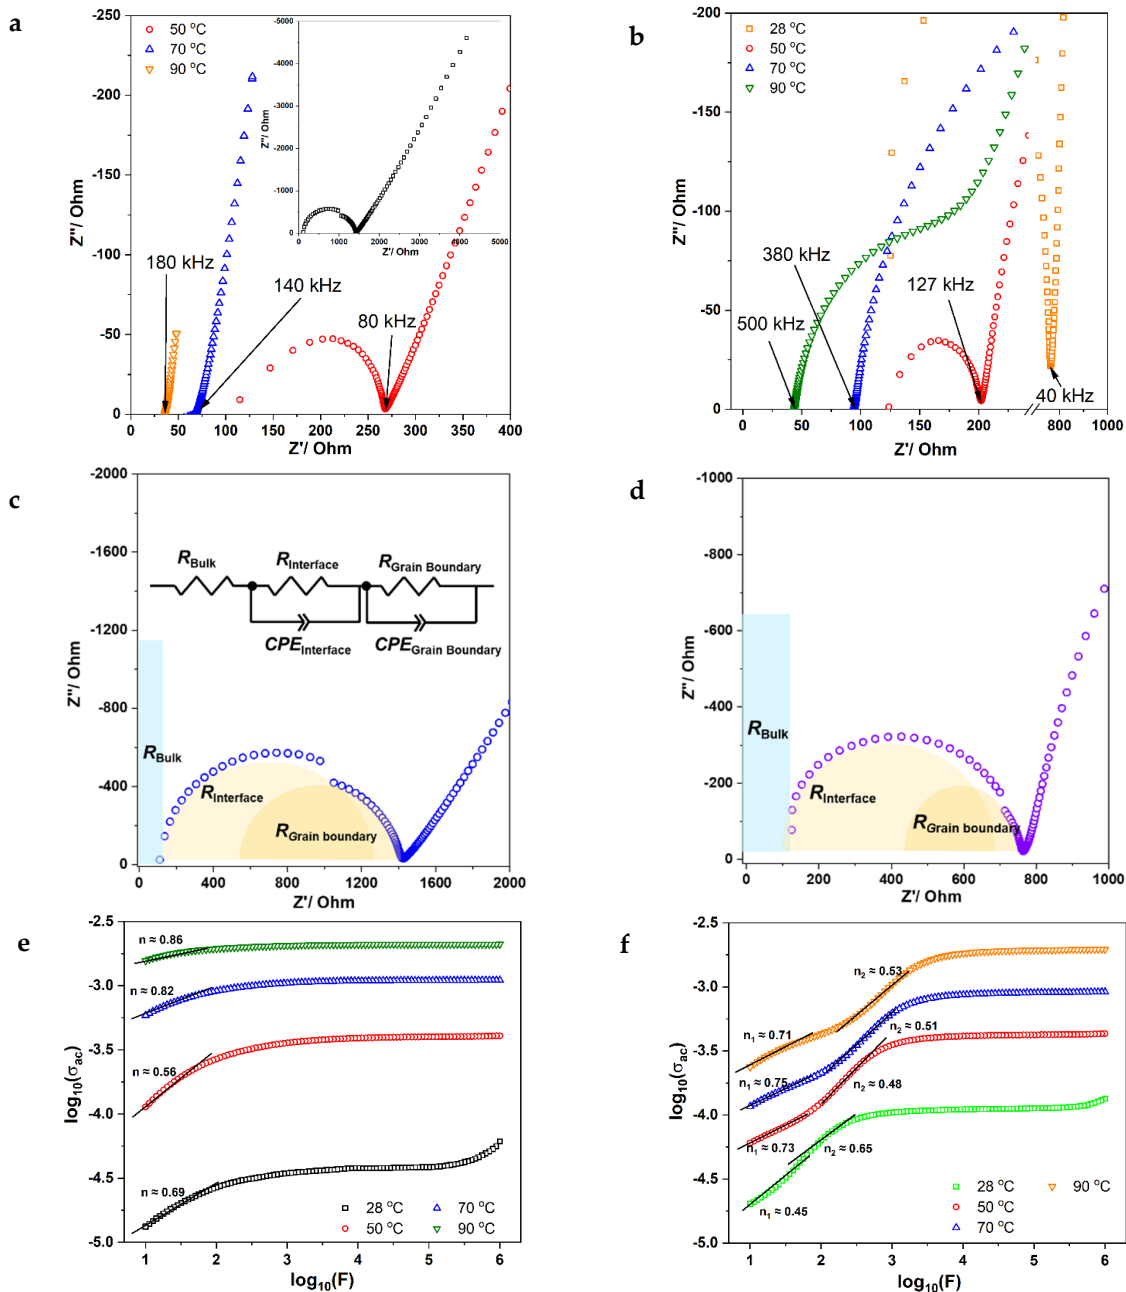

$\text{LiI}(80\text{Li}_2\text{S} - 20\text{AlI}_3) \cdot 10\text{LiI} \parallel \text{Li}$  and  $\text{LiI}(\text{Li}_6\text{PS}_5\text{Cl})(80\text{Li}_2\text{S} - 20\text{AlI}_3) \cdot 10\text{LiI} \parallel \text{Li}_6\text{PS}_5\text{Cl} \parallel \text{Li}$  symmetric cells were employed to investigate the stability of  $(80\text{Li}_2\text{S} - 20\text{AlI}_3) \cdot 10\text{LiI}$  at a low voltage region. The small inset in Figure 5a proved that the reaction between  $(80\text{Li}_2\text{S} - 20\text{AlI}_3) \cdot 10\text{LiI}$  and Li metal is irreversible. However, the  $\text{LiI}(\text{Li}_6\text{PS}_5\text{Cl})(80\text{Li}_2\text{S} - 20\text{AlI}_3) \cdot 10\text{LiI} \parallel \text{Li}_6\text{PS}_5\text{Cl} \parallel \text{Li}$  symmetric cell exhibited a relatively steady charge–discharge voltage for more than 200 h. These results indicated that  $(80\text{Li}_2\text{S} - 20\text{AlI}_3) \cdot 10\text{LiI}$  irreversibly reacts with Li metal, but it is quite stable in the low-voltage region. All-solid-state cells, which employed  $(80\text{Li}_2\text{S} - 20\text{AlI}_3) \cdot 10\text{LiI}$ , as solid electrolyte in the positive electrode, were fabricated to study their stability at high voltage regions.  $\text{CuS}$  and  $\text{Li}_{4.4}\text{Si}$  were used as active materials. Figure 5b–e illustrates the electrochemical performances of the prepared cells. The 1st and 10th charge–discharge curves of the cells cycling using CC and CC-CV modes are depicted in Figure 5b,d, respectively. Two distinct plateaus are observed in the discharge curves, which arise from the following reactions [37]:

The first plateau:  $\text{CuS} + 1.96\text{Li}^+ + 1.96\text{e}^- \rightarrow \text{Li}_2\text{S} + \text{Cu}_{1.96}\text{S}$ .

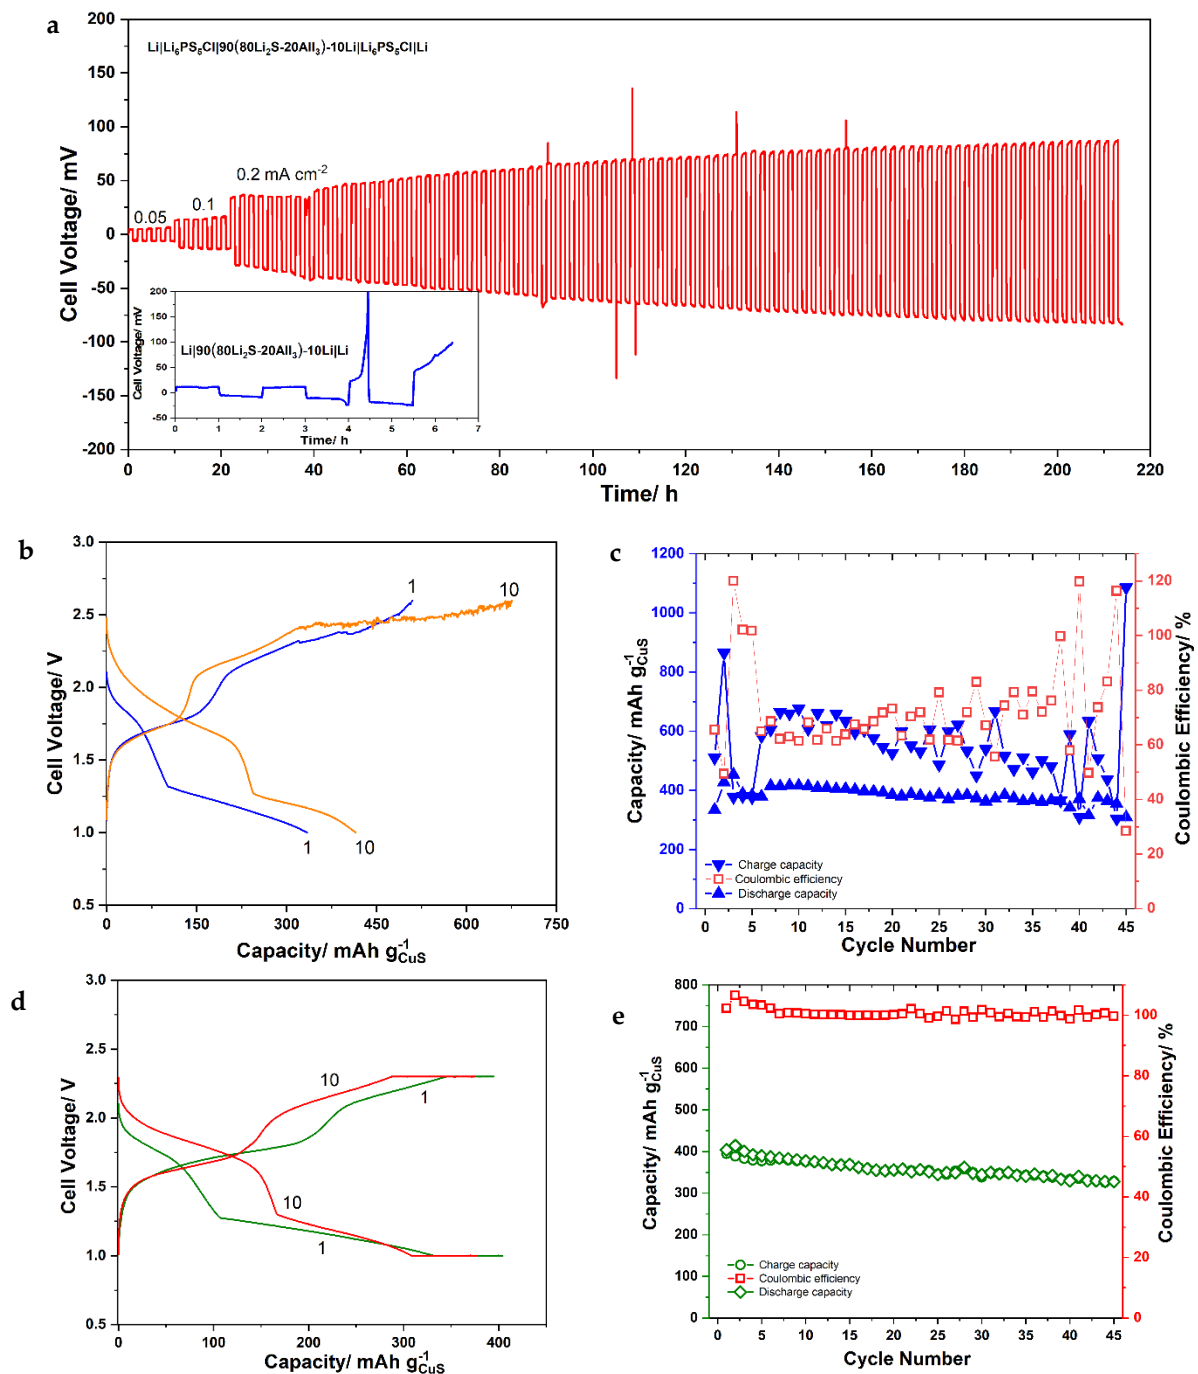

The second plateau:  $\text{Cu}_{1.96}\text{S} + 2\text{Li}^+ \rightarrow \text{Li}_2\text{S} + 1.96\text{Cu}$ .

Accordingly, two distinct plateaus also appeared in the charge curves. The charge curve in Figure 5b was smooth at low voltage and bumpy at voltage higher than 2.3 V, which illustrated the decomposition of  $(80\text{Li}_2\text{S} - 20\text{AlI}_3) \cdot 10\text{LiI}$  composite solid electrolyte. The discharge and charge capacity were about 400 and 600  $\text{mAh g}^{-1}\text{CuS}$ , respectively (Figure 5c), resulting in the capacity loss of about 200  $\text{mAh g}^{-1}\text{CuS}$  and unstable Coulombic efficiency (Figure 5c). Figure 5c indicates that the discharge capacity was stable at about 400  $\text{mAh g}^{-1}\text{CuS}$  but the charge capacity was unsteady, showing the continuous

decomposition of solid electrolyte. The cyclic voltammogram of  $\text{Li}_3\text{SI}$  solid electrolyte also indicated the oxidation of  $\text{S}^{2-}$  at about 2 V, which was one of the reasons for low capacity retention of the all-solid-state cell cycling in the voltage range of 2.0–3.6 V [24]. Thus,  $(80\text{Li}_2\text{S} - 20\text{AlI}_3) \cdot 10\text{LiI}$  composite solid electrolyte was irreversibly decomposed at voltage higher than 2.3 V. The cell cycling in CC-CV mode (CC:  $0.25 \text{ mA cm}^{-2}$ , CV: 2.30 V) exhibits smooth charge–discharge curves (Figure 5d), confirming that  $(80\text{Li}_2\text{S} - 20\text{AlI}_3) \cdot 10\text{LiI}$  was stable in this voltage region. The charge–discharge capacity was stable at about  $400 \text{ mAh g}^{-1}_{\text{CuS}}$ , resulting in a Coulombic efficiency higher than 99.5%.

**Figure 4.** (a) Nyquist plots of  $80\text{Li}_2\text{S} - 20\text{AlI}_3$  measured from 28 to 90 °C (the inset shows the Nyquist plot at 28 °C); (b) Nyquist plots of  $(80\text{Li}_2\text{S} - 20\text{AlI}_3) \cdot 10\text{LiI}$  measured from 28 to 90 °C; (c,d) the matching impedance figures, equivalent circuit of  $80\text{Li}_2\text{S} - 20\text{AlI}_3$  and  $(80\text{Li}_2\text{S} - 20\text{AlI}_3) \cdot 10\text{LiI}$  measured at 28 °C, respectively; (e) conductivity isotherms (10 Hz to 1 MHz) of  $80\text{Li}_2\text{S} - 20\text{AlI}_3$  measured from 28 to 90 °C; (f) conductivity isotherms (10 Hz to 1 MHz) of  $(80\text{Li}_2\text{S} - 20\text{AlI}_3) \cdot 5\text{LiI}$  measured from 28 to 90 °C.

**Figure 5.** (a) Cyclability of the symmetric  $\text{LiLi}_6\text{PS}_5\text{Cl}(90(80\text{Li}_2\text{S} - 20\text{AlI}_3) \cdot 10\text{Li})\text{Li}_6\text{PS}_5\text{ClLi}$  and  $\text{Li}(90(80\text{Li}_2\text{S} - 20\text{AlI}_3) \cdot 10\text{Li})\text{Li}$  (small inset); (b) 1st and 10th charge–discharge curves of the solid-state cell cycled using CC mode; (c) cyclic properties of the solid-state cell using CC mode; (d) 1st and 10th charge–discharge curves of the solid-state cell cycled using CC-CV mode; (e) cyclic properties of the solid-state cell using CC-CV mode.

#### 4. Conclusions

$(100 - x)\text{Li}_2\text{S} - x\text{AlI}_3$  and  $(80\text{Li}_2\text{S} - 20\text{AlI}_3) \cdot y\text{Li}$  ( $y = 0, 5, 10, 15$ ) composite solid electrolytes were successfully prepared by mechanochemical synthesis. XRD results revealed that  $\text{Li}_2\text{S}$  and  $\text{AlI}_3$  formed a solid solution, while  $\text{LiI}$  crystals remained in sample  $y = 15$ . It was also proved that  $(80\text{Li}_2\text{S} - 20\text{AlI}_3) \cdot 10\text{LiI}$  is a pure Li-ion conductor with the ionic conductivity of about  $2.3 \times 10^{-4} \text{ Scm}^{-1}$  at  $25^\circ\text{C}$ , about three times higher than that of the

80Li<sub>2</sub>S – 20AlI<sub>3</sub> sample. The impedance spectroscopy results revealed that LiI addition enhanced the grain boundary and interfacial resistance of the prepared samples. The results from XRD and AC impedance suggested that LiI might be present in the amorphous form in samples  $y = 5$  and 10. The symmetric and all-solid-state cell performance illustrated that (80Li<sub>2</sub>S – 20AlI<sub>3</sub>)-10LiI was relatively stable at voltage lower than 2.3 V.

**Author Contributions:** T.A.T. performed the experiments; N.H.H.P. conceived and designed the experiments, analyzed and interpreted the data, and wrote the paper; L.T.Q.A. and T.V.T. wrote, reviewed, and edited the paper. All authors have read and agreed to the published version of the manuscript.

**Funding:** This research received no external funding.
