Featured Application: The analysis of news sentiments presented in this article can be used for various research and practical applications. In this study, news sentiment analysis was used in order to perform more accurate forecasting of economic indicators. Based on the results obtained in the study, it can be seen that the negative sentiment index is strongly linked to economic indicators. Based on the value of the sentiment, for this reason, economic activity and individual indicators of economic activity can be predicted. It can be used in the activities of various decision-makers, banks, and state institutions.

Abstract: Natural language processing is a rapidly expanding field of artificial intelligence, the main goal of which is linguistics. This field allows various mathematical/computer science techniques to be applied to natural language processing. Sentiment analysis is one of the most common tasks that is solved based on natural language processing. The primary purpose of sentiment analysis is to determine the mood (happy, sad, angry, and others) or polarity (negative, neutral, positive) of the presented text. Based on the relevance of the application of natural language processing, this study aims to create a dataset of Lithuanian news and determine the sentiment of this news. Identified news sentiment is associated with different indicators of economic activity. More than 1 million articles (1,256,227) have been collected from the largest news portal. The articles were collected from the first month of 2006 to the fifth month of 2022. More than 20,000 different LSTM, GRU, and RNN models were built with different parameters and datasets (univariate, individual sentiments, all sentiments, clusters). Based on the obtained results, it can be observed that the inclusion of sentiments in clustering increased the accuracy of forecasting different economic activity indicators. The highest accuracy in all cases was obtained based on the best sentiment for individual time series.

1. Introduction

Natural language processing is a rapidly expanding field of artificial intelligence, the main goal of which is linguistics. This field allows various mathematical/computer science methods to be applied to natural language processing. Due to the rapid development of the field, natural language processing can be applied to a wide range of tasks: automatic translation [1], automatic correction of grammatical errors in texts [2], improving search engines based on natural language processing [3], voice-over text, and many other areas [4]. In addition, sentiment analysis is one of the most common tasks that is solved based on

natural language processing. The primary purpose of sentiment analysis is to determine a given text's mood (happy, sad, angry, etc.) or polarity (negative, neutral, positive). Such natural language processing allows for processing millions of texts and determining the sentiment of these texts [5]. Sentiment analysis is often used in corporate activities to analyze comments about goods, companies, or other items. Due to the high speed of analysis and possible determination of sentiment, sentiment analysis can also be used in economic activities when various publicly available sources are evaluated: Twitter messages, Facebook messages, reports in the press, and others. In order to determine the sentiment of economic news/texts, specific words that can describe the sentiment are quite often used, and the number of these words is determined [6]. The authors often analyze such words and combinations of words as economic recession, falling shares, war, political uncertainty, and others. An index is created based on the number of these words [7]. Recent scientific research proves the relevance of this field of science and application as more and more attention is paid to sentiment analysis applied to natural language processing. One such study is Shapiro et al. (2022), which applied both word-based computing and machine learning techniques [8]; other authors have carried out similar studies.

Based on the relevance of the application of natural language processing, this study aims to create a dataset of Lithuanian news and determine the sentiment of this news. The determined news sentiment was associated with different indicators of economic activity. It is important to note that the datasets in the studies conducted by other authors are relatively small, so this study will allow us to evaluate the impact of an extensive dataset on sentiment analysis. It is expected that this work will allow the evaluation of the impact of a negative sentiment about different news categories on economic activity. Based on this objective, this paper hypothesizes that increasing negative news sentiment is inversely related to economic activity indicators. This scientific work would allow assessing the influence of negative sentiments about Lithuanian news on economic indicators. It would contribute to the development of this science field, help make more accurate forecasts, and form further guidelines in this field of research.

2. Materials and Methods

This chapter reviews the materials and methods. In the first stage of this research, data were collected from the most prominent Lithuanian news portal. In order to collect this data, the Python package Playwright was used, which allows the data collection process to be automated. Each observation/text has three main parts: the title, the lead, and the full text of the article. This research used article titles and leads. In addition, information such as publication date and article category (such as business, health, sports, and others) was collected from the articles. More than 1 million articles (1,256,227) were collected from the largest news portal. The articles were collected from the first month of 2006 to the fifth month of 2022. Below is the number of articles collected from different periods (see Figure 1). Indicators of economic activity were collected using the database of the Lithuanian Statistics Department. Three leading indicators were chosen: monthly, annual, and production index. These data were chosen due to their current frequency, i.e., these data are available monthly.

This study used pre-trained transformer models for sentiment detection. In order to use the pre-trained transformer models, the collected texts were first translated into English. The translation into English was necessary because there are currently no existing quality models using the Lithuanian language. In order to ensure the accuracy of the translated texts, selected random texts were checked manually. Four different models of pre-trained transformers available in HuggingFace were used for sentiment analysis: DistilBERT-base-uncased, FinBERT, Twitter-roBERTa-base, and FinBERT-tone. The use of four different models is based on the fact that individual models may not always accurately determine sentiment due to the nature of their training, so combining different models allows for more accurate sentiment analysis and avoids individual models' influence. The DistilBERT-base-uncased model is a reduced version of the Bert-base-uncased model but

has exceptionally high performance. FinBERT is a model developed by Prosus, specifically designed to analyze financial texts. The third model used is FinBERT-tone, which is also trained on financial texts and determines financial texts' sentiment [9]. This study's last but not least model is the Twitter-roBERTa-base model, specifically for sentiment analysis [10]. This model is trained using as many as 124 million Twitter messages collected over three years. The last model was chosen for its ability to identify sentiment in standard texts. The resulting overall sentiment index was calculated based on the results of all four models. The general sentiment index (SI) for time t is calculated according to the formula below:

$$SI_t = \frac{1}{N_t} \sum_{j=1}^4 \sum_{i=1}^{N_t} T_j(A_{it}) \quad (1)$$

where SI_t is the sentiment index at a point in time t ; T_j —a sentiment analysis model (transformer) is used since the sum of the four models used in total is up to 4, $T_j(A_{it})$ and the output is given in the interval from 0 to 1; and A_{it} —the i th news article at time t , where i is in the interval from 1 to N_t , where N_t is the number of news articles at a time t .

Figure 1. Number of articles over time.

Below is the calculated sentiment index for the entire period under study. Based on the presented graph, it can be observed that the most significant increase in negative sentiment was observed after the start of the pandemic in early 2020 and also after the start of the war in Ukraine in early 2022 (Figures 2 and 3).

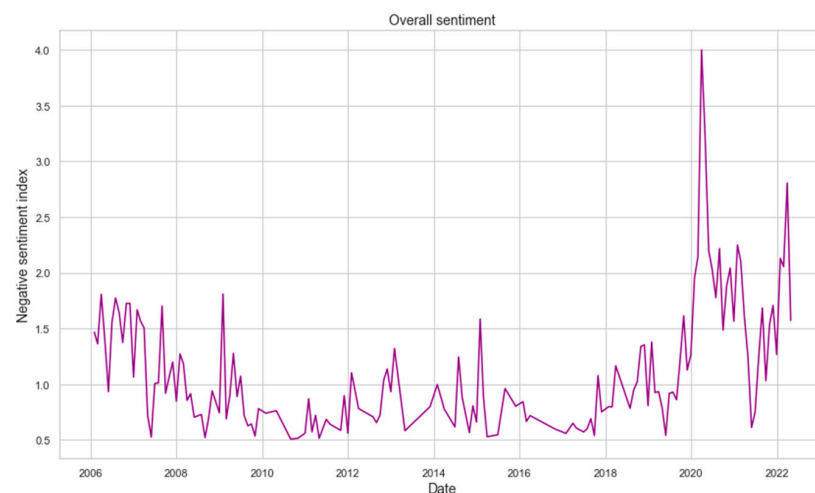

Figure 2. Negative overall sentiment over research period.

Figure 3. Negative business sentiment over the research period.

This study also used different clustering methods to classify various texts into certain unknown groups. Clustering methods such as MIDE [11], K-means, GMM, and BGMM were used in this study. Based on the clustering results, these results were also included in the forecasting of economic indicators.

3. Results

This section presents the main results of forecasting economic indicators based on sentiment and cluster analysis. These results were compared with the one-dimensional time series forecasting results. Economic indicators were forecasted using different lags (from 1 to 12 months). The following table (see Table 1) presents the results of the best models for each economic activity indicator. The first row shows the results of univariate forecasting, the second row shows the forecasting based on the best sentiment, the third row shows the forecasting based on all sentiments, and the last row shows the forecasting based on cluster analysis. More than 20,000 LSTM, GRU, and RNN models were created with different parameters and datasets (univariate, individual sentiments, all sentiments, and clusters). Based on the obtained results, it can be observed that the inclusion of sentiments in clustering increased the accuracy of forecasting different economic activity indicators. The highest accuracy in all cases was obtained based on the best sentiment for individual time series. It is also interesting that although the largest cluster improved the forecasting results, it was not better than the sentiment analysis results. This can be justified because only a tiny part of all texts belonged to the largest cluster, so they do not necessarily reflect the exact situation.

Table 1. Results of economic activity forecasting based on univariate time series and multivariate time series.

Data/Model	RMSE		MAE		MAPE	
	Mean	Std	Mean	Std	Mean	Std
Monthly inflation rate						
Univariate	0.217	0.016	0.153	0.008	0.348	0.017
Overall sentiment	0.134	0.005	0.097	0.002	0.243	0.011
All sentiments	0.219	0.011	0.159	0.006	0.379	0.034
Biggest cluster	0.218	0.014	0.109	0.007	0.345	0.047

Table 1. *Cont.*

Data/Model	RMSE		MAE		MAPE	
Annual inflation rate						
Univariate	0.097	0.015	0.064	0.015	0.303	0.050
Overall sentiment	0.072	0.009	0.051	0.007	0.293	0.045
All sentiments	0.116	0.061	0.088	0.048	0.301	0.127
Biggest cluster	0.126	0.067	0.087	0.051	0.305	0.168
Production index						
Univariate	0.224	0.013	0.187	0.015	0.446	0.041
Lithuania sentiment	0.099	0.005	0.079	0.005	0.162	0.012
All sentiments	0.152	0.012	0.088	0.011	0.177	0.013
Biggest cluster	0.166	0.024	0.093	0.022	0.198	0.022

bold values indicate the best model.

4. Discussion

In this study, the main objectives were implemented. One of the primary and most difficult tasks was to collect an extensive dataset and prepare it for further analysis. Although the collected dataset was large enough, it was planned to use even more extensive datasets and collect articles from different news portals in the final study. After forecasting based on data clustering and sentiment analysis, it was notable that the results obtained in the case of clustering were not as good as when using sentiment analysis of all the data. In the case of clustering, only the most significant data cluster was used, and for this reason, it can be assumed that the obtained results may not have been as accurate if a more significant number of clusters had been used. Taking into account the results obtained during the research, it was observed that forecasting economic indicators based on sentiment analysis was better than forecasting one-dimensional data. Therefore, the hypothesis raised during the research was confirmed. This suggests that continuous monitoring of news and analysis of these news sentiments can allow for more accurate forecasts of economic indicators compared to one-dimensional data. As a further direction of this research, it is expected to train new sentiment analysis models explicitly adapted to the Lithuanian language, which would allow comparing the results with the results obtained in this study. It can also be assumed that using the entire text of the article instead of the article title and lead could positively impact the research results. For this reason, further studies with even larger datasets are planned.
